March 21, 2022 at 18:49

1. Introduction. This is the CTWILL program by D. E. Knuth, based on CWEAVE by Silvio Levy and D. E. Knuth. It is also based on TWILL, a private WEB program that Knuth wrote to produce Volumes B and D of *Computers & Typesetting* in 1985. CTWILL was hacked together hastily in June, 1992, to generate pages for Knuth's book about the Stanford GraphBase, and updated even more hastily in March, 1993, to generate final copy for that book. The main idea was to extend CWEAVE so that "mini-indexes" could appear. No time was available to make CTWILL into a refined or complete system, nor even to fully update the program documentation below. Subsequent changes were made only to maintain compatibility with CWEAVE. Further information can be found in Knuth's article "Mini-indexes for literate programs," reprinted in *Digital Typography* (1999), 225–245.

A kind of "user manual" for CTWILL can be found in section ⟨ Mogrify CWEAVE into CTWILL 288 ⟩ and beyond, together with additional material specific to CTWILL.

Editor's Note: *This heavily redacted version of* `ctwill.pdf` *had to meddle with the section numbering of* `cweave.w`, *spreading tabular material over several sections and splitting long sections into smaller chunks in order to fix overful pages—both horizontally and vertically—, to make the overall appearance of the CTWILL documentation most pleasing to the readers' eyes.*

Please do not try to compare this `ctwill.pdf` *to the one created by CWEAVE instead of CTWILL; the section numbering will be quite "off" from* `cweave.w`. *Care has been taken to give a faithful overall rendering of CTWILL's code, though.* —*Enjoy!*

The "banner line" defined here should be changed whenever CTWILL is modified. The version number parallels the corresponding version of CWEAVE.

#**define** *banner* "This␣is␣CTWILL,␣Version␣4.7"
           ▷ will be extended by the TEX Live *versionstring* ◁

⟨ Include files 4 ⟩
⟨ Preprocessor definitions ⟩
⟨ Common code for CWEAVE and CTANGLE 3 ⟩
⟨ Typedef declarations 22 ⟩
⟨ Private variables 23 ⟩
⟨ Predeclaration of procedures 8 ⟩

2. **CWEAVE** has a fairly straightforward outline. It operates in three phases: First it
inputs the source file and stores cross-reference data, then it inputs the source once
again and produces the TEX output file, finally it sorts and outputs the index.

Please read the documentation for **COMMON**, the set of routines common to **CTANGLE**
and **CWEAVE**, before proceeding further.

```
int main (int ac,       ▷ argument count ◁
    char ∗∗av)       ▷ argument values ◁
{
    argc ← ac;  argv ← av;  program ← ctwill;  ⟨ Set initial values 24 ⟩
    common_init ( );  ⟨ Start TEX output 89 ⟩
    if (show_banner) cb_show_banner ( );       ▷ print a "banner line" ◁
    ⟨ Store all the reserved words 34 ⟩
    phase_one ( );       ▷ read all the user's text and store the cross-references ◁
    phase_two ( );       ▷ read all the text again and translate it to TEX form ◁
    phase_three ( );       ▷ output the cross-reference index ◁
    if (tracing ≡ fully ∧ ¬show_progress) new_line;
    return wrap_up ( );       ▷ and exit gracefully ◁
}
```

3. The next few sections contain stuff from the file `"common.w"` that must be
included in both `"ctangle.w"` and `"cweave.w"`. It appears in file `"common.h"`,
which is also included in `"common.w"` to propagate possible changes from this **COMMON**
interface consistently.

First comes general stuff:

⟨ Common code for **CWEAVE** and **CTANGLE** 3 ⟩ ≡
```
    typedef uint8_t eight_bits;
    typedef uint16_t sixteen_bits;
    typedef enum {
        ctangle, cweave, ctwill
    } cweb;
    extern cweb program;       ▷ CTANGLE or CWEAVE or CTWILL? ◁
    extern int phase;       ▷ which phase are we in? ◁
```
See also sections 5, 6, 7, 9, 10, 12, 14, 15, and 326.

This code is used in section 1.

4. You may have noticed that almost all `"strings"` in the `CWEB` sources are placed in the context of the '`_`' macro. This is just a shortcut for the '*gettext*' function from the "GNU gettext utilities." For systems that do not have this library installed, we wrap things for neutral behavior without internationalization. For backward compatibility with pre-ANSI compilers, we replace the "standard" header file '`stdbool.h`' with the KPATHSEA interface '`simpletypes.h`'.

#**define** _(s) *gettext*(s)

⟨ Include files 4 ⟩ ≡
#**include** `<ctype.h>`   ▷ definition of *isalpha*, *isdigit* and so on ◁
#**include** `<kpathsea/simpletypes.h>`   ▷ **boolean**, *true* and *false* ◁
#**include** `<stddef.h>`   ▷ definition of **ptrdiff_t** ◁
#**include** `<stdint.h>`   ▷ definition of **uint8_t** and **uint16_t** ◁
#**include** `<stdio.h>`   ▷ definition of *printf* and friends ◁
#**include** `<stdlib.h>`   ▷ definition of *getenv* and *exit* ◁
#**include** `<string.h>`   ▷ definition of *strlen*, *strcmp* and so on ◁

#**ifndef** HAVE_GETTEXT
#**define** HAVE_GETTEXT 0
#**endif**

#**if** HAVE_GETTEXT
#**include** `<libintl.h>`
#**else**
#**define** *gettext*(a) a
#**endif**

This code is used in section 1.

5. Code related to the character set:

#**define** *and_and* °4   ▷ '`&&`'; corresponds to MIT's ∧ ◁
#**define** *lt_lt* °20   ▷ '`<<`'; corresponds to MIT's ⊂ ◁
#**define** *gt_gt* °21   ▷ '`>>`'; corresponds to MIT's ⊃ ◁
#**define** *plus_plus* °13   ▷ '`++`'; corresponds to MIT's ↑ ◁
#**define** *minus_minus* °1   ▷ '`--`'; corresponds to MIT's ↓ ◁
#**define** *minus_gt* °31   ▷ '`->`'; corresponds to MIT's → ◁
#**define** *non_eq* °32   ▷ '`!=`'; corresponds to MIT's ≠ ◁
#**define** *lt_eq* °34   ▷ '`<=`'; corresponds to MIT's ≤ ◁
#**define** *gt_eq* °35   ▷ '`>=`'; corresponds to MIT's ≥ ◁
#**define** *eq_eq* °36   ▷ '`==`'; corresponds to MIT's ≡ ◁
#**define** *or_or* °37   ▷ '`||`'; corresponds to MIT's ∨ ◁
#**define** *dot_dot_dot* °16   ▷ '`...`'; corresponds to MIT's ∞ ◁

        ▷ number of identifiers, strings, section names; must be less than 10240 ◁
#**define** *max_sections* 4000   ▷ greater than the total number of sections ◁

18.   End of COMMON interface.

19.   The following parameters are sufficient to handle TEX (converted to CWEB), so they should be sufficient for most applications of CWEAVE.

#**define** *line_length* 80   ▷ lines of TEX output have at most this many characters; should
                be less than 256 ◁
#**define** *max_refs* 65535   ▷ number of cross-references; must be less than 65536 ◁
#**define** *max_scraps* 5000   ▷ number of tokens in C texts being parsed ◁

---

20.   Data structures exclusive to CWEAVE.   As explained in common.w, the field of a **name_info** structure that contains the *rlink* of a section name is used for a completely different purpose in the case of identifiers. It is then called the *ilk* of the identifier, and it is used to distinguish between various types of identifiers, as follows:

normal and *func_template* identifiers are part of the C program that will appear in italic type (or in typewriter type if all uppercase).

custom identifiers are part of the C program that will be typeset in special ways.

roman identifiers are index entries that appear after @^ in the CWEB file.

wildcard identifiers are index entries that appear after @: in the CWEB file.

typewriter identifiers are index entries that appear after @. in the CWEB file.

alfop, ..., *attr* identifiers are C or C++ reserved words whose *ilk* explains how they are to be treated when C code is being formatted.

#**define** *ilk*   *dummy.Ilk*
#**define** *normal* 0   ▷ ordinary identifiers have *normal* ilk ◁
#**define** *roman* 1   ▷ normal index entries have *roman* ilk ◁
#**define** *wildcard* 2   ▷ user-formatted index entries have *wildcard* ilk ◁
#**define** *typewriter* 3   ▷ 'typewriter type' entries have *typewriter* ilk ◁
#**define** *abnormal*(*a*) ((*a*)→*ilk* > *typewriter*)   ▷ tells if a name is special ◁
#**define** *func_template* 4   ▷ identifiers that can be followed by optional template ◁
#**define** *custom* 5   ▷ identifiers with user-given control sequence ◁
#**define** *alfop* 22   ▷ alphabetic operators like **and** or **not_eq** ◁

21.   We keep track of the current section number in *section_count*, which is the total number of sections that have started. Sections which have been altered by a change file entry have their *changed_section* flag turned on during the first phase—NOT!

22.   The other large memory area in `CWEAVE` keeps the cross-reference data. All uses of the name p are recorded in a linked list beginning at $p\rightarrow xref$, which points into the *xmem* array. The elements of *xmem* are structures consisting of an integer, *num*, and a pointer *xlink* to another element of *xmem*. If $x \leftarrow p\rightarrow xref$ is a pointer into *xmem*, the value of $x\rightarrow num$ is either a section number where p is used, or *cite_flag* plus a section number where p is mentioned, or *def_flag* plus a section number where p is defined; and $x\rightarrow xlink$ points to the next such cross-reference for p, if any. This list of cross-references is in decreasing order by section number. The next unused slot in *xmem* is *xref_ptr*. The linked list ends at $\&xmem[0]$.

The global variable *xref_switch* is set either to *def_flag* or to zero, depending on whether the next cross-reference to an identifier is to be underlined or not in the index. This switch is set to *def_flag* when `@!` or `@d` is scanned, and it is cleared to zero when the next identifier or index entry cross-reference has been made. Similarly, the global variable *section_xref_switch* is either *def_flag* or *cite_flag* or zero, depending on whether a section name is being defined, cited or used in C text.

This code is used in section 2.

25.   A new cross-reference for an identifier is formed by calling *new_xref*, which discards duplicate entries and ignores non-underlined references to one-letter identifiers or C's reserved words.

If the user has sent the *no_xref* flag (the -x option of the command line), it is unnecessary to keep track of cross-references for identifiers. If one were careful, one could probably make more changes around section 115 to avoid a lot of identifier looking up.

#**define** *append_xref*(*c*)
         if (*xref_ptr* ≡ *xmem_end*) *overflow*(_("cross-reference"));
         else (++*xref_ptr*)→*num* ← *c*

#**define** *is_tiny*(*p*) *length*(*p*) ≡ 1
#**define** *unindexed*(*a*) ((*a*) < *res_wd_end* ∧ (*a*)→*ilk* ≥ *custom*)
         ▷ tells if uses of a name are to be indexed ◁

⟨Predeclaration of procedures 8⟩ +≡
   static void *new_xref*(**name_pointer**);
   static void *new_section_xref*(**name_pointer**);
   static void *set_file_flag*(**name_pointer**);

26.   **static void** *new_xref*(**name_pointer** *p*)
   {
      xref_pointer *q*;   ▷ pointer to previous cross-reference ◁
      sixteen_bits *m*, *n*;   ▷ new and previous cross-reference value ◁

      if (*no_xref*) **return**;
      if ((*unindexed*(*p*) ∨ *is_tiny*(*p*)) ∧ *xref_switch* ≡ 0) **return**;
      m ← *section_count* + *xref_switch*; *xref_switch* ← 0; *q* ← (**xref_pointer**) *p*→*xref*;
      if (*q* ≠ *xmem*) {
         n ← *q*→*num*;
         if (*n* ≡ *m* ∨ *n* ≡ *m* + *def_flag*) **return**;
         else if (*m* ≡ *n* + *def_flag*) {
            q→*num* ← *m*; **return**;
         }
      }
      append_xref(*m*); *xref_ptr*→*xlink* ← *q*; *update_node*(*p*);
   }

27.   The cross-reference lists for section names are slightly different. Suppose that a section name is defined in sections $m_1, \ldots, m_k$, cited in sections $n_1, \ldots, n_l$, and used in sections $p_1, \ldots, p_j$. Then its list will contain $m_1 + def\_flag, \ldots, m_k + def\_flag$, $n_1 + cite\_flag, \ldots, n_l + cite\_flag, p_1, \ldots, p_j$, in this order.

Although this method of storage takes quadratic time with respect to the length of the list, under foreseeable uses of CWEAVE this inefficiency is insignificant.

```
static void new_section_xref (name_pointer p)
{
    xref_pointer q ← (xref_pointer) p→xref ;
    xref_pointer r ← xmem ;        ▷ pointers to previous cross-references ◁
    if (q > r)
        while (q→num > section_xref_switch ) {
            r ← q;  q ← q→xlink ;
        }
    if (r→num ≡ section_count + section_xref_switch ) return ;
            ▷ don't duplicate entries ◁
    append_xref (section_count + section_xref_switch );  xref_ptr→xlink ← q;
    section_xref_switch ← 0;
    if (r ≡ xmem ) update_node (p);
    else  r→xlink ← xref_ptr ;
}
```

28.   The cross-reference list for a section name may also begin with *file_flag*. Here's how that flag gets put in.

```
static void set_file_flag (name_pointer p)
{
    xref_pointer q ← (xref_pointer) p→xref ;
    if (q→num ≡ file_flag ) return ;
    append_xref (file_flag );  xref_ptr→xlink ← q;  update_node (p);
}
```

29.   A third large area of memory is used for sixteen-bit 'tokens', which appear in short lists similar to the strings of characters in *byte_mem*. Token lists are used to contain the result of C code translated into TEX form; further details about them will be explained later. A **text_pointer** variable is an index into *tok_start*.

⟨ Typedef declarations 22 ⟩ +≡
```
    typedef sixteen_bits token;
    typedef token *token_pointer;
    typedef token_pointer *text_pointer;
```

32.   Here are the three procedures needed to complete *id_lookup*:

  boolean *names_match*(**name_pointer** *p*,   ▷ points to the proposed match ◁
      const char *∗first*,   ▷ position of first character of string ◁
      size_t *l*,   ▷ length of identifier ◁
      eight_bits *t*)   ▷ desired *ilk* ◁
  {
    if (*length*(*p*) ≠ *l*) **return** *false*;
    if (*p⃗ilk* ≠ *t* ∧ ¬(*t* ≡ *normal* ∧ *abnormal*(*p*))) **return** *false*;
    return ¬*strncmp*(*first*, *p⃗byte_start*, *l*);
  }
  void *init_p*(**name_pointer** *p*, **eight_bits** *t*)
  {
    struct perm_meaning *∗q* ← *get_meaning*(*p*);
    p⃗ilk ← *t*; *init_node*(*p*); *q⃗stamp* ← 0; *q⃗link* ← Λ; *q⃗perm.id* ← *p*;
    q⃗perm.prog_no ← *q⃗perm.sec_no* ← 0; *strcpy*(*q⃗perm.tex_part*, "\\uninitialized");
  }
  void *init_node*(**name_pointer** *p*)
  {
    p⃗xref ← (**void** *∗*) *xmem*;
  }

33.   And here are two small helper functions to simplify the code.

#**define** *update_node*(*p*) (*p*)⃗*xref* ← (**void** *∗*) *xref_ptr*
#**define** *get_meaning*(*p*) (*p*) − *name_dir* + *cur_meaning*

34.   We have to get C's and C++'s reserved words into the hash table, and the simplest way to do this is to insert them every time CWEAVE is run. Fortunately there are relatively few reserved words. (Some of these are not strictly "reserved," but are defined in header files of the ISO Standard C Library. An ever growing list of C++ keywords can be found here: `https://en.cppreference.com/w/cpp/keyword`.)

This code is used in section 2.

35. Lexical scanning. Let us now consider the subroutines that read the CWEB source file and break it into meaningful units. There are four such procedures: One simply skips to the next '@␣' or '@*' that begins a section; another passes over the TEX text at the beginning of a section; the third passes over the TEX text in a C comment; and the last, which is the most interesting, gets the next token of a C text. They all use the pointers *limit* and *loc* into the line of input currently being studied.

36. Control codes in CWEB, which begin with '@', are converted into a numeric code designed to simplify CWEAVE's logic; for example, larger numbers are given to the control codes that denote more significant milestones, and the code of *new_section* should be the largest of all. Some of these numeric control codes take the place of **char** control codes that will not otherwise appear in the output of the scanning routines.

39. Users can write @2, @1, and @0 to turn tracing *fully* on, *partly* on, and *off*, respectively.

⟨ Special control codes for debugging 39 ⟩ ≡
  ccode['0'] ← *ccode*['1'] ← *ccode*['2'] ← *trace*;

This code is used in section 38.

40. The *skip_limbo* routine is used on the first pass to skip through portions of the input that are not in any sections, i.e., that precede the first section. After this procedure has been called, the value of *input_has_ended* will tell whether or not a section has actually been found.

There's a complication that we will postpone until later: If the @s operation appears in limbo, we want to use it to adjust the default interpretation of identifiers.

⟨ Predeclaration of procedures 8 ⟩ +≡
  static void *skip_limbo*(**void**);
  static eight_bits *skip_TEX*(**void**);

---

eight_bits = **uint8_t**, §3.   COMMON.W §25.   *off* = 0, §201.
fully = 2, §201.   *limit*: **char** *, COMMON.W §22.   *partly* = 1, §201.
input_has_ended: **boolean**,   *loc*: **char** *, COMMON.W §22.

41. We look for a clue about the program's title, because this will become part of all meanings.

static void *skip_limbo* (**void**)
{
  while (*true*) {
    if (*loc* > *limit* ∧ *get_line* ( ) ≡ *false*) **return**;
    if (*loc* ≡ *buffer* ∧ *strncmp* (*buffer*, "\\def\\title{", 11) ≡ 0) {
      loc ← *buffer* + 10; *title_lookup* ( );   ▷ this program's title will be code zero ◁
    }
    ∗(*limit* + 1) ← '@';
    while (∗*loc* ≠ '@') *loc* ++;   ▷ look for '@', then skip two chars ◁
    if (*loc* ++ ≤ *limit*)
      switch (*ccode* [(**eight_bits**) ∗*loc* ++]) {
      case *new_section*: **return**;
      case *noop*: *skip_restricted* ( ); **break**;
      case *format_code*: ⟨ Process simple format in limbo 79 ⟩
      }
  }
}

42. The *skip_TEX* routine is used on the first pass to skip through the TEX code at the beginning of a section. It returns the next control code or '|' found in the input. A *new_section* is assumed to exist at the very end of the file.

format *skip_TeX* *TeX*

static eight_bits *skip_TEX* (**void**)
{
  while (*true*) {
    if (*loc* > *limit* ∧ *get_line* ( ) ≡ *false*) **return** *new_section*;
    ∗(*limit* + 1) ← '@';
    while (∗*loc* ≠ '@' ∧ ∗*loc* ≠ '|') *loc* ++;
    if (∗*loc* ++ ≡ '|') **return** (**eight_bits**) '|';
    if (*loc* ≤ *limit*) **return** *ccode* [(**eight_bits**) ∗(*loc* ++)];
  }
}

43. Inputting the next token. As stated above, CWEAVE's most interesting lexical scanning routine is the *get_next* function that inputs the next token of C input. However, *get_next* is not especially complicated.

The result of *get_next* is either a **char** code for some special character, or it is a special code representing a pair of characters (e.g., '!='), or it is the numeric value computed by the *ccode* table, or it is one of the following special codes:

identifier: In this case the global variables *id_first* and *id_loc* will have been set to the beginning and ending-plus-one locations in the buffer, as required by the *id_lookup* routine.

string: The string will have been copied into the array *section_text*; *id_first* and *id_loc* are set as above (now they are pointers into *section_text*).

constant: The constant is copied into *section_text*, with slight modifications; *id_first* and *id_loc* are set.

Furthermore, some of the control codes cause *get_next* to take additional actions:

xref_roman, *xref_wildcard*, *xref_typewriter*, *TEX_string*, *meaning*, *suppress*, and *verbatim*: The values of *id_first* and *id_loc* will have been set to the beginning and ending-plus-one locations in the buffer.

section_name: In this case the global variable *cur_section* will point to the *byte_start* entry for the section name that has just been scanned. The value of *cur_section_char* will be '(' if the section name was preceded by @(instead of @<.

If *get_next* sees '@!' it sets *xref_switch* to *def_flag* and goes on to the next token.

>   **return** *c*;
>   }
> }

45.   ⟨ Predeclaration of procedures 8 ⟩ +≡   **static eight_bits** *get_next*(**void**);

46.   Because preprocessor commands do not fit in with the rest of the syntax of C, we have to deal with them separately. One solution is to enclose such commands between special markers. Thus, when a **#** is seen as the first character of a line, *get_next* returns a special code *left_preproc* and raises a flag *preprocessing*.

   We can use the same internal code number for *left_preproc* as we do for *ord*, since *get_next* changes *ord* into a string.

#**define** *left_preproc* *ord*   ▷ begins a preprocessor command ◁
#**define** *right_preproc* °*223*   ▷ ends a preprocessor command ◁
⟨ Private variables 23 ⟩ +≡
   static boolean *preprocessing* ← *false*;   ▷ are we scanning a preprocessor command? ◁

47.   ⟨ Raise preprocessor flag 47 ⟩ ≡
> {
>   *preprocessing* ← *true*; ⟨ Check if next token is **include** 49 ⟩
>   **return** *left_preproc*;
> }

This code is used in section 44.

48.   An additional complication is the freakish use of **<** and **>** to delimit a file name in lines that start with **#include**. We must treat this file name as a string.

⟨ Private variables 23 ⟩ +≡
   static boolean *sharp_include_line* ← *false*;   ▷ are we scanning a #**include** line? ◁

49.   ⟨ Check if next token is **include** 49 ⟩ ≡
   while (*loc* ≤ *buffer_end* − 7 ∧ *xisspace*(∗*loc*)) *loc* ++;
   if (*loc* ≤ *buffer_end* − 6 ∧ *strncmp*(*loc*, "include", 7) ≡ 0) *sharp_include_line* ← *true*;

This code is used in section 47.

50.   When we get to the end of a preprocessor line, we lower the flag and send a
code *right_preproc*, unless the last character was a \.

⟨ Check if we're at the end of a preprocessor command 50 ⟩ ≡
   while (*loc* ≡ *limit* − 1 ∧ *preprocessing* ∧ ∗*loc* ≡ '\\')
       if (*get_line*( ) ≡ *false*) **return** *new_section*;   ▷ still in preprocessor mode ◁
   if (*loc* ≥ *limit* ∧ *preprocessing*) {
       preprocessing ← *sharp_include_line* ← *false*; **return** *right_preproc*;
   }

This code is used in section 44.

53. Different conventions are followed by TEX and C to express octal and hexadecimal numbers; it is reasonable to stick to each convention within its realm. Thus the C part of a CWEB file has octals introduced by 0 and hexadecimals by 0x, but CWEAVE will print with TEX macros that the user can redefine to fit the context. In order to simplify such macros, we replace some of the characters.

On output, the ␣ that replaces ' in C++ literals will become "\␣".

Notice that in this section and the next, *id_first* and *id_loc* are pointers into the array *section_text*, not into *buffer*.

71. The *C_xref* subroutine stores references to identifiers in C text material beginning with the current value of *next_control* and continuing until *next_control* is '{' or '|', or until the next "milestone" is passed (i.e., $next\_control \geq format\_code$). If $next\_control \geq format\_code$ when *C_xref* is called, nothing will happen; but if $next\_control \equiv \text{'|'}$ upon entry, the procedure assumes that this is the '|' preceding C text that is to be processed.

The parameter *spec_ctrl* is used to change this behavior. In most cases *C_xref* is called with $spec\_ctrl \equiv ignore$, which triggers the default processing described above. If $spec\_ctrl \equiv section\_name$, section names will be gobbled. This is used when C text in the TEX part or inside comments is parsed: It allows for section names to appear in | . . . |, but these strings will not be entered into the cross reference lists since they are not definitions of section names.

The program uses the fact that our internal code numbers satisfy the relations $xref\_roman \equiv identifier + roman$ and $xref\_wildcard \equiv identifier + wildcard$ and $xref\_typewriter \equiv identifier + typewriter$, as well as $normal \equiv 0$.

⟨Predeclaration of procedures 8⟩ +≡
  static void *C_xref* (**eight_bits**);
  static void *outer_xref* (**void**);

72.   **static void** *C_xref* (▷ makes cross-references for C identifiers ◁
      eight_bits *spec_ctrl*)
  {
    while (*next_control* < *format_code* ∨ *next_control* ≡ *spec_ctrl*) {
      if (*next_control* ≥ *identifier* ∧ *next_control* ≤ *xref_typewriter*) {
        if (*next_control* > *identifier*) ⟨Replace '@@' by '@' 75⟩
        new_xref (*id_lookup* (*id_first*, *id_loc*, *next_control* − *identifier*));
      }
      if (*next_control* ≡ *section_name*) {
        section_xref_switch ← *cite_flag*;   *new_section_xref* (*cur_section*);
      }
      next_control ← *get_next* ( );
      if (*next_control* ≡ '|' ∨ *next_control* ≡ *begin_comment*
          ∨ *next_control* ≡ *begin_short_comment*) **return**;
    }
  }

73. The *outer_xref* subroutine is like *C_xref* except that it begins with *next_control* ≠ '|' and ends with $next\_control \geq format\_code$. Thus, it handles C text with embedded comments.

  static void *outer_xref* (**void**)   ▷ extension of *C_xref* ◁
  {
    int *bal*;   ▷ brace level in comment ◁
    while (*next_control* < *format_code*)
      if (*next_control* ≠ *begin_comment* ∧ *next_control* ≠ *begin_short_comment*)
        C_xref (*ignore*);
      else {
        boolean *is_long_comment* ← (*next_control* ≡ *begin_comment*);
        bal ← *copy_comment* (*is_long_comment*, 1);   *next_control* ← '|';

```
        while (bal > 0) {
            C_xref(section_name);        ▷ do not reference section names in comments ◁
            if (next_control ≡ '|') bal ← copy_comment(is_long_comment, bal);
            else bal ← 0;        ▷ an error message will occur in phase two ◁
        }
    }
}
```

74.   In the TEX part of a section, cross-reference entries are made only for the
identifiers in C texts enclosed in | ... |, or for control texts enclosed in @^ ... @> or
@. ... @> or @: ... @>.

⟨ Store cross-references in the TEX part of a section 74 ⟩ ≡
```
    while (true) {
        switch (next_control ← skip_TEX()) {
        case translit_code: err_print(_("!␣Use␣@l␣in␣limbo␣only")); continue;
        case underline: xref_switch ← def_flag; continue;
        case trace: tracing ← *(loc − 1) − '0'; continue;
        case '|': C_xref(section_name); break;
        case xref_roman: case xref_wildcard: case xref_typewriter: case meaning:
            case suppress: case noop: case section_name: loc −= 2;
            next_control ← get_next();        ▷ scan to @> ◁
            if (next_control ≥ xref_roman ∧ next_control ≤ xref_typewriter) {
                ⟨ Replace '@@' by '@'  75 ⟩
                new_xref(id_lookup(id_first, id_loc, next_control − identifier));
            }
            break;
        }
        if (next_control ≥ format_code) break;
    }
```
This code is used in section 70.
```

---

**75.**  ⟨ Replace '`@@`' by '`@`' 75 ⟩ ≡
  {
     **char** ∗*src* ← *id_first*, ∗*dst* ← *id_first*;
     **while** (*src* < *id_loc*) {
        **if** (∗*src* ≡ '`@`') *src* ++;
        ∗*dst* ++ ← ∗*src* ++;
     }
     *id_loc* ← *dst*;
     **while** (*dst* < *src*) ∗*dst* ++ ← '␣';        ▷ clean up in case of error message display ◁
  }

This code is used in sections 72 and 74.

**76.**    During the definition and C parts of a section, cross-references are made for all identifiers except reserved words. However, the right identifier in a format definition is not referenced, and the left identifier is referenced only if it has been explicitly underlined (preceded by `@!`). The TEX code in comments is, of course, ignored, except for C portions enclosed in | . . . |; the text of a section name is skipped entirely, even if it contains | . . . | constructions.

The variables *lhs* and *rhs* point to the respective identifiers involved in a format definition.

⟨ Private variables 23 ⟩ +≡
   **static name_pointer** *lhs*, *rhs*;        ▷ pointers to *byte_start* for format identifiers ◁
   **static name_pointer** *res_wd_end*;        ▷ pointer to the first nonreserved identifier ◁

**77.**    When we get to the following code we have *next_control* ≥ *format_code*.

⟨ Store cross-references in the definition part of a section 77 ⟩ ≡
   **while** (*next_control* ≤ *definition*) {        ▷ *format_code* or *definition* ◁
      **if** (*next_control* ≡ *definition*) {
         *xref_switch* ← *def_flag*;        ▷ implied `@!` ◁
         *next_control* ← *get_next*( );
      }
      **else** ⟨ Process a format definition 78 ⟩
      *outer_xref*( );
   }

This code is used in section 70.

**78.**    Error messages for improper format definitions will be issued in phase two. Our job in phase one is to define the *ilk* of a properly formatted identifier, and to remove cross-references to identifiers that we now discover should be unindexed.

⟨ Process a format definition 78 ⟩ ≡
   {
      *next_control* ← *get_next*( );
      **if** (*next_control* ≡ *identifier*) {
         *lhs* ← *id_lookup*(*id_first*, *id_loc*, *normal*); *lhs*→*ilk* ← *normal*;
         **if** (*xref_switch*) *new_xref*(*lhs*);
         *next_control* ← *get_next*( );
         **if** (*next_control* ≡ *identifier*) {
            *rhs* ← *id_lookup*(*id_first*, *id_loc*, *normal*); *lhs*→*ilk* ← *rhs*→*ilk*;

```
        if (unindexed(lhs)) {          ▷ retain only underlined entries ◁
           xref_pointer q, r ← Λ;
           for (q ← (xref_pointer) lhs→xref; q > xmem; q ← q→xlink)
              if (q→num < def_flag)
                 if (r) r→xlink ← q→xlink;
                 else lhs→xref ← (void *) q→xlink;
              else r ← q;
        }
        next_control ← get_next();
     }
   }
}
```

This code is used in section 77.

79. A much simpler processing of format definitions occurs when the definition is found in limbo.

⟨ Process simple format in limbo 79 ⟩ ≡
```
   if (get_next() ≠ identifier) err_print(_("!␣Missing␣left␣identifier␣of␣@s"));
   else {
      lhs ← id_lookup(id_first, id_loc, normal);
      if (get_next() ≠ identifier) err_print(_("!␣Missing␣right␣identifier␣of␣@s"));
      else {
         rhs ← id_lookup(id_first, id_loc, normal); lhs→ilk ← rhs→ilk;
      }
   }
```

This code is used in section 41.

           if (∗*j*−− ≡ '%' ∧ (*j* ≡ *out_buf* ∨ ∗*j* ≠ '\\')) {
              ∗*b*−− ← '%'; **break**;
           }
     if (*b* < *out_ptr*) *memcpy* (*out_buf* + 1, *b* + 1, (**size_t**)(*out_ptr* − *b*));
     out_ptr −= *b* − *out_buf* ;
  }

88.   When we are copying TₑX source material, we retain line breaks that occur in the input, except that an empty line is not output when the TₑX source line was nonempty. For example, a line of the TₑX file that contains only an index cross-reference entry will not be copied. The *finish_line* routine is called just before *get_line* inputs a new line, and just after a line break token has been emitted during the output of translated C text.

  static void *finish_line* (**void**)   ▷ do this at the end of a line ◁
  {
     char ∗*k*;   ▷ pointer into *buffer* ◁
     if (*out_ptr* > *out_buf*) *flush_buffer* (*out_ptr*, *false*, *false*);
     else {
        for (*k* ← *buffer*; *k* ≤ *limit*; *k*++)
           if (¬(*xisspace* (∗*k*))) **return**;
        flush_buffer (*out_buf* , *false*, *false*);
     }
  }

89.   In particular, the *finish_line* procedure is called near the very beginning of phase two. We initialize the output variables in a slightly tricky way so that the first line of the output file will be dependent of the user language set by the '+l' option and its argument. If you call CTWILL with '+lX' (or '−lX' as well), where 'X' is the (possibly empty) string of characters to the right of 'l', 'X' will be prepended to 'ctwimac.tex', e.g., if you call CTWILL with '+ldeutsch', you will receive the line '\input deutschctwimac'. Without this option the first line of the output file will be '\input ctwimac'. Or, if the user has specified proofing by saying +P on the command line, it's '\input ctproofmac' (resp. \input Xctproofmac with option +lX), a set of macros used when debugging mini-index entries.

  #**define** *proofing* *flags* ['P']

⟨ Start TEX output 89 ⟩ ≡
   $out\_ptr \leftarrow out\_buf + 1$; $out\_line \leftarrow 1$; $active\_file \leftarrow tex\_file$; tex_puts("\\input␣");
   tex_printf ($use\_language$); tex_puts ($proofing$? "ctproofma" : "ctwima"); $*out\_ptr \leftarrow$ 'c';
This code is used in section 2.

90.   When we wish to append one character c to the output buffer, we write '$out(c)$'; this will cause the buffer to be emptied if it was already full. If we want to append more than one character at once, we say $out\_str(s)$, where s is a string containing the characters.

A line break will occur at a space or after a single-nonletter TEX control sequence.

#**define** $out(c)$
          {
             if (ms_mode) {   ▷ outputting to $ministring\_buf$ ◁
                if ($ministring\_ptr < ministring\_buf\_end$) $*ministring\_ptr ++ \leftarrow c$;
             }
             else {
                if ($out\_ptr \geq out\_buf\_end$) $break\_out($);
                $*(++ out\_ptr) \leftarrow c$;
             }
          }
⟨ Predeclaration of procedures 8 ⟩ +≡
   static void out_str(**const char** ∗);
   static void $break\_out$(**void**);

91.   **static void** out_str (▷ output characters from s to end of string ◁
       const char ∗s)
   {
      while (∗s) $out(*s ++)$;
   }

92.   The $break\_out$ routine is called just before the output buffer is about to overflow. To make this routine a little faster, we initialize position 0 of the output buffer to '\'; this character isn't really output.

98. Routines that copy TEX material. During phase two, we use the sub-routines *copy_limbo* and *copy_TEX* (and *copy_comment*) in place of the analogous *skip_limbo* and *skip_TEX* that were used in phase one.

The *copy_limbo* routine, for example, takes TEX material that is not part of any section and transcribes it almost verbatim to the output file. The use of '@' signs is severely restricted in such material: '@@' pairs are replaced by singletons; '@l' and '@q' and '@s' are interpreted.

⟨ Predeclaration of procedures 8 ⟩ +≡
  static void *copy_limbo*(**void**);
  static eight_bits *copy_TEX*(**void**);
  static int *copy_comment*(**boolean**, **int**);

99.   **static void** *copy_limbo*(**void**)
  {
    while (*true*) {
      if (*loc* > *limit* ∧ (*finish_line*( ), *get_line*( ) ≡ *false*)) **return**;
      ∗(*limit* + 1) ← '@';
      while (∗*loc* ≠ '@') *out*(∗(*loc* ++));
      if (*loc* ++ ≤ *limit*) {
        switch (*ccode*[(**eight_bits**) ∗*loc* ++]) {
        case *new_section*: **return**;
        case *translit_code*: *out_str*("\\ATL"); **break**;
        case '@': *out*('@'); **break**;
        case *noop*: *skip_restricted*( ); **break**;
        case *format_code*:
          if (*get_next*( ) ≡ *identifier*) *get_next*( );
          if (*loc* ≥ *limit*) *get_line*( );   ▷ avoid blank lines in output ◁
          break;   ▷ the operands of @s are ignored on this pass ◁
        case *right_start*: *right_start_switch* ← *true*; **break**;
        default: *err_print*(_("!␣Double␣@␣should␣be␣used␣in␣limbo")); *out*('@');
        }
      }
    }
  }

100.   The *copy_TEX* routine processes the TEX code at the beginning of a section; for example, the words you are now reading were copied in this way. It returns the next control code or '|' found in the input. We don't copy spaces or tab marks into the beginning of a line. This makes the test for empty lines in *finish_line* work.

format *copy_TeX*   *TeX*

static eight_bits *copy_TEX* (**void**)
{
   char *c*;   ▷ current character being copied ◁

   while (*true*) {
     if (*loc* > *limit* ∧ (*finish_line*( ), *get_line*( ) ≡ *false*)) **return** *new_section*;
     ∗(*limit* + 1) ← '@';
     while ((*c* ← ∗(*loc* ++)) ≠ '|' ∧ *c* ≠ '@') {
       out(*c*);
       if (*out_ptr* ≡ *out_buf* + 1 ∧ (*xisspace*(*c*))) *out_ptr* −−;
     }
     if (*c* ≡ '|') **return** '|';
     if (*loc* ≤ *limit*) **return** *ccode*[(**eight_bits**) ∗(*loc* ++)];
   }
}

101. The *copy_comment* function issues a warning if more braces are opened than closed, and in the case of a more serious error it supplies enough braces to keep TEX from complaining about unbalanced braces. Instead of copying the TEX material into the output buffer, this function copies it into the token memory (in phase two only). The abbreviation *app_tok*(*t*) is used to append token *t* to the current token list, and it also makes sure that it is possible to append at least one further token without overflow.

#**define** *app_tok*(*c*)
          {
             if (*tok_ptr* + 2 > *tok_mem_end*) *overflow*(("token"));
             ∗(*tok_ptr* ++) ← *c*;
          }
  static int *copy_comment*(▷ copies TEX code in comments ◁
        boolean *is_long_comment*,   ▷ is this a traditional C comment? ◁
        int *bal*)   ▷ brace balance ◁
  {
     char *c*;   ▷ current character being copied ◁
     while (*true*) {
        if (*loc* > *limit*) {
           if (*is_long_comment*) {
              if (*get_line*( ) ≡ *false*) {
                 err_print(("! Input ended in mid-comment")); *loc* ← *buffer* + 1;
                 goto *done*;
              }
           } **else** {
              if (*bal* > 1) *err_print*(("! Missing } in comment"));
              goto *done*;
           }
        }
        c ← ∗(*loc* ++);
        if (*c* ≡ '|') **return** *bal*;
        if (*is_long_comment*) ⟨Check for end of comment 102⟩

           if (*ishigh*(*c*)) *app_tok*(*quoted_char*);
           app_tok(*c*);
        }
        ⟨Copy special things when *c* ≡ '@', '\\' 103⟩
        if (*c* ≡ '{') *bal* ++;
        else if (*c* ≡ '}') {
           if (*bal* > 1) *bal* −−;
           else {
              err_print(("! Extra } in comment"));
              if (*phase* ≡ 2) *tok_ptr* −−;
           }
        }
     }
  done: ⟨Clear *bal* and **return** 104⟩
  }

102.   ⟨Check for end of comment 102⟩ ≡
  if (c ≡ '*' ∧ *loc ≡ '/') {
    loc ++;
    if (bal > 1) err_print(_("!␣Missing␣}␣in␣comment"));
    goto done;
  }

This code is used in section 101.

103.   ⟨Copy special things when c ≡ '@', '\\' 103⟩ ≡
  if (c ≡ '@') {
    if (*(loc ++) ≠ '@') {
      err_print(_("!␣Illegal␣use␣of␣@␣in␣comment")); loc −= 2;
      if (phase ≡ 2) *(tok_ptr − 1) ← '␣';
      goto done;
    }
  }
  else {
    if (c ≡ '\\' ∧ *loc ≠ '@') {
      if (phase ≡ 2) app_tok(*(loc ++));
      else loc ++;
    }
  }

This code is used in section 101.

104.   We output enough right braces to keep TEX happy.

⟨Clear bal and **return** 104⟩ ≡
  if (phase ≡ 2)
    while (bal −− > 0) app_tok('}');
  return 0;

This code is used in section 101.

105. Parsing. The most intricate part of CWEAVE is its mechanism for converting C-like code into TEX code, and we might as well plunge into this aspect of the program now. A "bottom up" approach is used to parse the C-like material, since CWEAVE must deal with fragmentary constructions whose overall "part of speech" is not known.

At the lowest level, the input is represented as a sequence of entities that we shall call *scraps*, where each scrap of information consists of two parts, its *category* and its *translation*. The category is essentially a syntactic class, and the translation is a token list that represents TEX code. Rules of syntax and semantics tell us how to combine adjacent scraps into larger ones, and if we are lucky an entire C text that starts out as hundreds of small scraps will join together into one gigantic scrap whose translation is the desired TEX code. If we are unlucky, we will be left with several scraps that don't combine; their translations will simply be output, one by one.

The combination rules are given as context-sensitive productions that are applied from left to right. Suppose that we are currently working on the sequence of scraps $s_1 \, s_2 \ldots s_n$. We try first to find the longest production that applies to an initial substring $s_1 \, s_2 \ldots$; but if no such productions exist, we try to find the longest production applicable to the next substring $s_2 \, s_3 \ldots$; and if that fails, we try to match $s_3 \, s_4 \ldots$, etc.

A production applies if the category codes have a given pattern. For example, one of the productions (see rule 3) is

$$ exp \; \left\{ \begin{array}{c} binop \\ ubinop \end{array} \right\} \; exp \; \rightarrow \; exp $$

and it means that three consecutive scraps whose respective categories are *exp*, *binop* (or *ubinop*), and *exp* are converted to one scrap whose category is *exp*. The translations of the original scraps are simply concatenated. The case of

$$ exp \; comma \; exp \; \rightarrow \; exp \qquad E_1 C \, opt9 \, E_2 $$

(rule 4) is only slightly more complicated: Here the resulting *exp* translation consists not only of the three original translations, but also of the tokens *opt* and 9 between the translations of the *comma* and the following *exp*. In the TEX file, this will specify an optional line break after the comma, with penalty 90.

At each opportunity the longest possible production is applied. For example, if the current sequence of scraps is *if_clause stmt else_like if_like*, rule 63 is applied; but if the sequence is *if_clause stmt else_like* followed by anything other than *if_like*, rule 64 takes effect; and if the sequence is *if_clause stmt* followed by anything other than *else_like*, rule 65 takes effect.

Translation rules such as '$E_1 C \, opt9 \, E_2$' above use subscripts to distinguish between translations of scraps whose categories have the same initial letter; these subscripts are assigned from left to right.

106.   Here is a list of the category codes that scraps can have. (A few others, like
int_like, have already been defined; the *cat_name* array contains a complete list.)

#**define** *exp* 1   ▷ denotes an expression, including perhaps a single identifier ◁
#**define** *unop* 2   ▷ denotes a unary operator ◁
#**define** *binop* 3   ▷ denotes a binary operator ◁
#**define** *ubinop* 4
              ▷ denotes an operator that can be unary or binary, depending on context ◁
#**define** *cast* 5   ▷ denotes a cast ◁
#**define** *question* 6   ▷ denotes a question mark and possibly the expressions flanking it ◁
#**define** *lbrace* 7   ▷ denotes a left brace ◁
#**define** *rbrace* 8   ▷ denotes a right brace ◁
#**define** *decl_head* 9   ▷ denotes an incomplete declaration ◁

108. This code allows CWEAVE to display its parsing steps.

#**define** $print\_cat(c)$ $fputs(cat\_name[c], stdout)$ ▷ symbolic printout of a category ◁

109.   The token lists for translated TEX output contain some special control symbols as well as ordinary characters. These control symbols are interpreted by `CWEAVE` before they are written to the output file.

break_space denotes an optional line break or an en space;

force denotes a line break;

big_force denotes a line break with additional vertical space;

preproc_line denotes that the line will be printed flush left;

opt denotes an optional line break (with the continuation line indented two ems with respect to the normal starting position)—this code is followed by an integer n, and the break will occur with penalty $10n$;

backup denotes a backspace of one em;

cancel obliterates any *break_space*, *opt*, *force*, or *big_force* tokens that immediately precede or follow it and also cancels any *backup* tokens that follow it;

indent causes future lines to be indented one more em;

outdent causes future lines to be indented one less em;

dindent causes future lines to be indented two more ems.

---

110. All of these tokens are removed from the TEX output that comes from C text between | . . . | signs; *break_space* and *force* and *big_force* become single spaces in this mode. The translation of other C texts results in TEX control sequences \1, \2, \3, \4, \5, \6, \7, \8 corresponding respectively to *indent*, *outdent*, *opt*, *backup*, *break_space*, *force*, *big_force* and *preproc_line*. However, a sequence of consecutive '␣', *break_space*, *force*, and/or *big_force* tokens is first replaced by a single token (the maximum of the given ones).

A *dindent* token becomes \1\1. It is equivalent to a pair of *indent* tokens. However, if *dindent* immediately precedes *big_force*, the two tokens are swapped, so that the indentation happens after the line break.

The token *math_rel* will be translated into \MRL{, and it will get a matching } later. Other control sequences in the TEX output will be '\\{ . . . }' surrounding identifiers, '\&{ . . . }' surrounding reserved words, '\.{ . . . }' surrounding strings, '\C{ . . . } *force*' surrounding comments, and '\X*n*: . . . \X' surrounding section names, where n is the section number.

#**define** *math_rel* °*206*
#**define** *big_cancel* °*210*   ▷ like *cancel*, also overrides spaces ◁
#**define** *cancel* °*211*   ▷ overrides *backup*, *break_space*, *force*, *big_force* ◁

111. From raw input to scraps.   The raw input is converted into scraps according to the following table, which gives category codes followed by the translations. The symbol '**' stands for '\&{identifier}', i.e., the identifier itself treated as a reserved word. The right-hand column is the so-called *mathness*, which is explained further below.

An identifier *c* of length 1 is translated as \|c instead of as \\{c}. An identifier CAPS in all caps is translated as \.{CAPS} instead of as \\{CAPS}. An identifier that has become a reserved word via **typedef** is translated with \& replacing \\ and *raw_int* replacing *exp*.

A string of length greater than 20 is broken into pieces of size at most 20 with discretionary breaks in between.

The construction `@t` stuff `@>` contributes `\hbox{` stuff `}` to the following scrap.

117. Table of all productions. Each production that combines two or more consecutive scraps implicitly inserts a `$` where necessary, that is, between scraps whose abutting boundaries have different *mathness*. In this way we never get double `$$`.

A translation is provided when the resulting scrap is not merely a juxtaposition of the scraps it comes from. An asterisk* next to a scrap means that its first identifier gets an underlined entry in the index, via the function *make_underlined*. Two asterisks** means that both *make_underlined* and *make_reserved* are called; that is, the identifier's ilk becomes *raw_int*. A dagger † before the production number refers to the notes at the end of this section, which deal with various exceptional cases.

We use *in*, *out*, *back*, *bsp*, and *din* as shorthands for *indent*, *outdent*, *backup*, *break_space*, and *dindent*, respectively.

125. †**Notes**

Rules 1, 38, 52, and 73: The *din*s and *out*s are suppressed if `CWEAVE` has been invoked with the `-i` option.

Rule 35: The *exp* must not be immediately followed by *lpar*, *lbrack*, *exp*, or *cast*.

Rule 41: The *big_force* becomes *force* if `CWEAVE` has been invoked with the `-o` option.

Rule 48: The *exp* or *int_like* must not be immediately followed by *base*.

Rule 76: The *force* in the *stmt* line becomes *bsp* if `CWEAVE` has been invoked with the `-f` option, and the *big_force* in the *decl* and *function* lines becomes *force* if `CWEAVE` has been invoked with the `-o` option.

Rule 78: The *define_like* case calls *make_underlined* on the following scrap.

Rule 94: The *new_like* must not be immediately followed by *lpar*.

Rule 99: The *new_exp* must not be immediately followed by *raw_int*, *struct_like*, or *colcol*.

Rule 110: The *raw_int* must not be immediately followed by *langle*.

Rule 111: The operator after *operator_like* must not be immediately followed by a *binop*.

Rule 114: The *operator_like* must not be immediately followed by *raw_ubin*.

Rule 123: The mathness of the *colon* or *base* changes to 'yes'.

Rules 153, 154: *make_reserved* is called only if `CWEAVE` has been invoked with the `+t` option.

Rule 200: The *exp* must not be immediately followed by *lpar* or *exp*.

Rule 202: The *raw_int* must be immediately followed by *semi* or *comma*.

126. Implementing the productions.   More specifically, a scrap is a structure consisting of a category *cat* and a **text_pointer** *trans*, which points to the translation in *tok_start*. When C text is to be processed with the grammar above, we form an array *scrap_info* containing the initial scraps. Our production rules have the nice property that the right-hand side is never longer than the left-hand side. Therefore it is convenient to use sequential allocation for the current sequence of scraps. Five pointers are used to manage the parsing:

pp is a pointer into *scrap_info*. We will try to match the category codes $pp{\rightarrow}cat$, $(pp + 1){\rightarrow}cat$, ... to the left-hand sides of productions.

scrap_base, *lo_ptr*, *hi_ptr*, and *scrap_ptr* are such that the current sequence of scraps appears in positions *scrap_base* through *lo_ptr* and *hi_ptr* through *scrap_ptr*, inclusive, in the *cat* and *trans* arrays. Scraps located between *scrap_base* and *lo_ptr* have been examined, while those in positions $\geq hi\_ptr$ have not yet been looked at by the parsing process.

Initially *scrap_ptr* is set to the position of the final scrap to be parsed, and it doesn't change its value. The parsing process makes sure that $lo\_ptr \geq pp + 3$, since productions have as many as four terms, by moving scraps from *hi_ptr* to *lo_ptr*. If there are fewer than $pp + 3$ scraps left, the positions up to $pp + 3$ are filled with blanks that will not match in any productions. Parsing stops when $pp \equiv lo\_ptr + 1$ and $hi\_ptr \equiv scrap\_ptr + 1$.

Since the *scrap* structure will later be used for other purposes, we declare its second element as a union.

  case inserted: printf ("[inserted]"); break;
  default: putchar ((int) r);
  }
```

This code is used in section 130.

---

132.   The production rules listed above are embedded directly into `CWEAVE`, since it is easier to do this than to write an interpretive system that would handle production systems in general. Several macros are defined here so that the program for each production is fairly short.

All of our productions conform to the general notion that some k consecutive scraps starting at some position j are to be replaced by a single scrap of some category c whose translation is composed from the translations of the disappearing scraps. After this production has been applied, the production pointer pp should change by an amount d. Such a production can be represented by the quadruple (j, k, c, d). For example, the production '*exp comma exp $\rightarrow$ exp*' would be represented by '$(pp, 3, exp, -2)$'; in this case the pointer pp should decrease by 2 after the production has been applied, because some productions with *exp* in their second or third positions might now match, but no productions have *exp* in the fourth position of their left-hand sides. Note that the value of d is determined by the whole collection of productions, not by an individual one. The determination of d has been done by hand in each case, based on the full set of productions but not on the grammar of C or on the rules for constructing the initial scraps.

We also attach a serial number to each production, so that additional information is available when debugging. For example, the program below contains the statement '*reduce*$(pp, 3, exp, -2, 4)$' when it implements the production just mentioned.

Before calling *reduce*, the program should have appended the tokens of the new translation to the *tok_mem* array. We commonly want to append copies of several existing translations, and macros are defined to simplify these common cases. For example, *big_app2*(pp) will append the translations of two consecutive scraps, $pp\text{-}trans$ and $(pp + 1)\text{-}trans$, to the current token list. If the entire new translation is formed in this way, we write '*squash*(j, k, c, d, n)' instead of '*reduce*(j, k, c, d, n)'. For example, '*squash*$(pp, 3, exp, -2, 3)$' is an abbreviation for '*big_app3*(pp)' followed by '*reduce*$(pp, 3, exp, -2, 3)$'.

A couple more words of explanation: Both *big_app* and *app* append a token (while *big_app1* to *big_app4* append the specified number of scrap translations) to the current token list. The difference between *big_app* and *app* is simply that *big_app* checks whether there can be a conflict between math and non-math tokens, and intercalates a '$' token if necessary. When in doubt what to use, use *big_app*.

\#**define** *app*(a) $*(tok\_ptr \mathbin{++}) \leftarrow (\textbf{token})(a)$
\#**define** *big_app2*(a) *big_app1*(a); *big_app1*$(a + 1)$
\#**define** *big_app3*(a) *big_app2*(a); *big_app1*$(a + 2)$
\#**define** *big_app4*(a) *big_app3*(a); *big_app1*$(a + 3)$
\#**define** *big_app1_insert*(p, c) *big_app1*(p); *big_app*(c); *big_app1*$(p + 1)$

⟨ Predeclaration of procedures 8 ⟩ +≡
  static void *app_str*(**const char** $*$);
  static void *big_app*(**token**);
  static void *big_app1*(**scrap_pointer**);

133.   The *mathness* is an attribute of scraps that says whether they are to be printed in a math mode context or not. It is separate from the "part of speech" (the *cat*) because to make each *cat* have a fixed *mathness* (as in the original WEAVE) would multiply the number of necessary production rules.

The low two bits (i.e., *mathness* % 4) control the left boundary. (We need two bits because we allow cases *yes_math*, *no_math* and *maybe_math*, which can go either way.) The next two bits (i.e., *mathness*/4) control the right boundary. If we combine two scraps and the right boundary of the first has a different mathness from the left boundary of the second, we insert a $ in between. Similarly, if at printing time some irreducible scrap has a *yes_math* boundary the scrap gets preceded or followed by a $. The left boundary is *maybe_math* if and only if the right boundary is.

#**define** *no_math* 2   ▷ should be in horizontal mode ◁
#**define** *yes_math* 1   ▷ should be in math mode ◁
#**define** *maybe_math* 0   ▷ works in either horizontal or math mode ◁

This code is used in section 135.

137.   In C, new specifier names can be defined via **typedef**, and we want to make the parser recognize future occurrences of the identifier thus defined as specifiers. This is done by the procedure *make_reserved*, which changes the *ilk* of the relevant identifier.

We first need a procedure to recursively seek the first identifier in a token list, because the identifier might be enclosed in parentheses, as when one defines a function returning a pointer.

If the first identifier found is a keyword like '**case**', we return the special value *case_found*; this prevents underlining of identifiers in case labels.

If the first identifier is the keyword '**operator**', we give up; users who want to index definitions of overloaded C++ operators should say, for example, '`@!@^\&{operator} $+{=}$@>`' (or, properly alphabetized, '`@!@:operator+=}{\&{operator} $+{=}$@>`').

#**define** *no_ident_found* (**token_pointer**) 0   ▷ distinct from any identifier token ◁
#**define** *case_found* (**token_pointer**) 1   ▷ likewise ◁
#**define** *operator_found* (**token_pointer**) 2   ▷ likewise ◁

⟨Predeclaration of procedures 8⟩ +≡
    static token_pointer *find_first_ident*(**text_pointer**);
    static void *make_reserved*(**scrap_pointer**);
    static void *make_underlined*(**scrap_pointer**);
    static void *underline_xref*(**name_pointer**);

138.   **static token_pointer** *find_first_ident*(**text_pointer** *p*)
{
    token_pointer *q*;   ▷ token to be returned ◁
    token_pointer *j*;   ▷ token being looked at ◁
    sixteen_bits *r*;   ▷ remainder of token after the flag has been stripped off ◁
    if ($p \geq text\_ptr$) *confusion*("`find_first_ident`");
    for ($j \leftarrow *p$; $j < *(p+1)$; j++) {
      $r \leftarrow *j \% id\_flag$;
      switch ($*j/id\_flag$) {
      case 2:   ▷ *res_flag* ◁
        if ($name\_dir[r].ilk \equiv case\_like$) **return** *case_found*;
        if ($name\_dir[r].ilk \equiv operator\_like$) **return** *operator_found*;
        if ($name\_dir[r].ilk \neq raw\_int$) **break**;
        `/*␣else␣fall␣through␣*/`
      case 1: **return** *j*;
      case 4: **case** 5:   ▷ *tok_flag* or *inner_tok_flag* ◁
        if (($q \leftarrow find\_first\_ident(tok\_start + r)) \neq no\_ident\_found$) **return** *q*;
        `/*␣else␣fall␣through␣*/`
      default: ;   ▷ char, *section_flag*, fall thru: move on to next token ◁
        if ($*j \equiv inserted$) **return** *no_ident_found*;   ▷ ignore inserts ◁
        else if ($*j \equiv qualifier$) j++;   ▷ bypass namespace qualifier ◁
      }
    }
    return *no_ident_found*;
}

139.   The scraps currently being parsed must be inspected for any occurrence of the identifier that we're making reserved; hence the **for** loop below. We use the fact that *make_underlined* has been called immediately preceding *make_reserved*, hence *tok_loc* has been set.

    static token_pointer *tok_loc*;   ▷ where the first identifier appears ◁
    static void *make_reserved*(▷ make the first identifier in *p⃗trans* like **int** ◁
        scrap_pointer *p*)
{
    sixteen_bits *tok_value*;   ▷ the name of this identifier, plus its flag ◁
    if ($tok\_loc \leq operator\_found$) **return**;   ▷ this should not happen ◁
    $tok\_value \leftarrow *tok\_loc$;
    for (; $p \leq scrap\_ptr$; $p \equiv lo\_ptr\ ?\ p \leftarrow hi\_ptr : p$++)
      if ($p{\rightarrow}cat \equiv exp$)
        if ($**(p{\rightarrow}trans) \equiv tok\_value$) {
          $p{\rightarrow}cat \leftarrow raw\_int$; $**(p{\rightarrow}trans) \leftarrow tok\_value \% id\_flag + res\_flag$;
        }
    $(name\_dir + (\textbf{sixteen\_bits})(tok\_value \% id\_flag)){\rightarrow}ilk \leftarrow raw\_int$;
    $*tok\_loc \leftarrow tok\_value \% id\_flag + res\_flag$;
}

140.   In the following situations we want to mark the occurrence of an identifier as a definition: when *make_reserved* is just about to be used; after a specifier, as in **char** $**argv$; before a colon, as in *found*:; and in the declaration of a function, as in *main*()\{...;\}. This is accomplished by the invocation of *make_underlined* at appropriate times. Notice that, in the declaration of a function, we find out that the identifier is being defined only after it has been swallowed up by an *exp*.

> **static void** *make_underlined*(▷ underline the entry for the first identifier in *p→trans* ◁
>   **scrap_pointer** *p*)
> \{
>   **if** ((*tok_loc* ← *find_first_ident*(*p→trans*)) ≤ *operator_found*) **return**;
>   ▷ this happens, for example, in **case** *found*: ◁
>   *xref_switch* ← *def_flag*; *underline_xref*(*tok_loc* % *id_flag* + *name_dir*);
> \}

141.   We cannot use *new_xref* to underline a cross-reference at this point because this would just make a new cross-reference at the end of the list. We actually have to search through the list for the existing cross-reference.

> **static void** *underline_xref*(**name_pointer** *p*)
> \{
>   **xref_pointer** *q* ← (**xref_pointer**) *p→xref*;
>   ▷ pointer to cross-reference being examined ◁
>   **xref_pointer** *r*;   ▷ temporary pointer for permuting cross-references ◁
>   **sixteen_bits** *m*;   ▷ cross-reference value to be installed ◁
>   **sixteen_bits** *n*;   ▷ cross-reference value being examined ◁
>   **if** (*no_xref*) **return**;
>   *m* ← *section_count* + *xref_switch*;
>   **while** (*q* ≠ *xmem*) \{
>   *n* ← *q→num*;
>   **if** (*n* ≡ *m*) **return**;
>   **else if** (*m* ≡ *n* + *def_flag*) \{

142. We get to this section only when the identifier is one letter long, so it didn't get a non-underlined entry during phase one. But it may have got some explicitly underlined entries in later sections, so in order to preserve the numerical order of the entries in the index, we have to insert the new cross-reference not at the beginning of the list (namely, at $p\text{-}xref$), but rather right before q.

⟨ Insert new cross-reference at q, not at beginning of list 142 ⟩ ≡

  else *reduce*(*pp*, 0, *exp*, −2, 150);
This code is used in section 136.

196.　The '*freeze_text*' macro is used to give official status to a token list. Before saying *freeze_text*, items are appended to the current token list, and we know that the eventual number of this token list will be the current value of *text_ptr*. But no list of that number really exists as yet, because no ending point for the current list has been stored in the *tok_start* array. After saying *freeze_text*, the old current token list becomes legitimate, and its number is the current value of *text_ptr* − 1 since *text_ptr* has been increased. The new current token list is empty and ready to be appended to. Note that *freeze_text* does not check to see that *text_ptr* hasn't gotten too large, since it is assumed that this test was done beforehand.

#**define** *freeze_text* *(++*text_ptr*) ← *tok_ptr*

⟨ Predeclaration of procedures 8 ⟩ +≡
  static void *reduce*(**scrap_pointer**, **short**, **eight_bits**, **short**, **short**);
  static void *squash*(**scrap_pointer**, **short**, **eight_bits**, **short**, **short**);

197.   Now here's the *reduce* procedure used in our code for productions, which takes advantage of the simplification that occurs when $k \equiv 0$.

```
static void reduce(scrap_pointer j, short k, eight_bits c, short d, short n)
{
    scrap_pointer i, i1;      ▷ pointers into scrap memory ◁

    j→cat ← c;
    if (k > 0) {
        j→trans ← text_ptr;  j→mathness ← 4 * cur_mathness + init_mathness;  freeze_text;
    }
    if (k > 1) {
        for (i ← j + k, i1 ← j + 1; i ≤ lo_ptr; i++, i1++) {
            i1→cat ← i→cat;  i1→trans ← i→trans;  i1→mathness ← i→mathness;
        }
        lo_ptr ← lo_ptr − k + 1;
    }
    pp ← (pp + d < scrap_base ? scrap_base : pp + d);
    ⟨Print a snapshot of the scrap list if debugging 202⟩
    pp −−;      ▷ we next say pp ++ ◁
}
```

198.   And here's the *squash* procedure, which combines big_app_k and *reduce* for matching numbers k.

```
static void squash(scrap_pointer j, short k, eight_bits c, short d, short n)
{
    switch (k) {
    case 1: big_app1(j); break;
    case 2: big_app2(j); break;
    case 3: big_app3(j); break;
    case 4: big_app4(j); break;
    default: confusion("squash");
    }
    reduce(j, k, c, d, n);
}
```

199. And here now is the code that applies productions as long as possible. Before applying the production mechanism, we must make sure it has good input (at least four scraps, the length of the lhs of the longest rules), and that there is enough room in the memory arrays to hold the appended tokens and texts. Here we use a very conservative test; it's more important to make sure the program will still work if we change the production rules (within reason) than to squeeze the last bit of space from the memory arrays.

    }
    if $(hi\_ptr \leq scrap\_ptr)$ $printf\,(\texttt{"..."})$;   ▷ indicate that more is coming ◁
  }
This code is used in section 197.

203.   The *translate* function assumes that scraps have been stored in positions *scrap_base* through *scrap_ptr* of *cat* and *trans*. It applies productions as much as possible. The result is a token list containing the translation of the given sequence of scraps.

After calling *translate*, we will have $text\_ptr + 3 \leq max\_texts$ and $tok\_ptr + 6 \leq max\_toks$, so it will be possible to create up to three token lists with up to six tokens without checking for overflow. Before calling *translate*, we should have $text\_ptr < max\_texts$ and $scrap\_ptr < max\_scraps$, since *translate* might add a new text and a new scrap before it checks for overflow.

  static text_pointer $translate(\textbf{void})$ ▷ converts a sequence of scraps ◁

  }

This code is used in section 203.

208. Initializing the scraps. If we are going to use the powerful production mechanism just developed, we must get the scraps set up in the first place, given a C text. A table of the initial scraps corresponding to C tokens appeared above in the section on parsing; our goal now is to implement that table. We shall do this by implementing a subroutine called *C_parse* that is analogous to the *C_xref* routine used during phase one.

Like *C_xref*, the *C_parse* procedure starts with the current value of *next_control* and it uses the operation *next_control* ← *get_next*( ) repeatedly to read C text until encountering the next '|' or '/*', or until *next_control* ≥ *format_code*. The scraps corresponding to what it reads are appended into the *cat* and *trans* arrays, and *scrap_ptr* is advanced.

```
static void C_parse(      ▷ creates scraps from C tokens ◁
    eight_bits spec_ctrl)
{
  while (next_control < format_code ∨ next_control ≡ spec_ctrl) {
    ⟨Append the scrap appropriate to next_control  211⟩
    next_control ← get_next( );
    if (next_control ≡ '|' ∨ next_control ≡ begin_comment
          ∨ next_control ≡ begin_short_comment) return;
  }
}
```

209. ⟨Predeclaration of procedures 8⟩ +≡ **static void** *C_parse*(**eight_bits**);

210. The following macro is used to append a scrap whose tokens have just been appended:

```
#define app_scrap(c, b)
        {
          (++scrap_ptr)→cat ← (c);  scrap_ptr→trans ← text_ptr;
          scrap_ptr→mathness ← 5 ∗ (b);      ▷ no no, yes yes, or maybe maybe ◁
          freeze_text;
        }
```

  case *minus_gt_ast*: *app_str*("\\MGA"); *app_scrap*(*binop*, *yes_math*); **break**;

This code is used in section 211.

215. The following code must use *app_tok* instead of *app* in order to protect against overflow. Note that $tok\_ptr + 1 \leq max\_toks$ after *app_tok* has been used, so another *app* is legitimate before testing again.

Many of the special characters in a string must be prefixed by '\' so that TEX will print them properly.

⟨ Append a string or constant 215 ⟩ ≡
  {
    int *count* ← −1;   ▷ characters remaining before string break ◁
    switch (*next_control*) {
    case *constant*: *app_str*("\\T{"); **break**;
    case *string*: *count* ← 20; *app_str*("\\.{"); **break**;
    default: *app_str*("\\vb{");
    }
    while (*id_first* < *id_loc*) {
      if (*count* ≡ 0) {   ▷ insert a discretionary break in a long string ◁
        app_str("}\\)\\.{"); *count* ← 20;
      }
      switch (∗*id_first*) {
      case '␣': **case** '\\': **case** '#': **case** '$': **case** '^': **case** '{': **case** '}':
        case '~': **case** '&': **case** '_': *app*('\\'); **break**;
      case '%':
        if (*next_control* ≡ *constant*) {
          app_str("}\\p{");   ▷ special macro for 'hex exponent' ◁
          id_first++;   ▷ skip '%' ◁
        }
        else *app*('\\');
        break;

```
        case '@':
          if (∗(id_first + 1) ≡ '@') id_first ++;
          else err_print(_("!␣Double␣@␣should␣be␣used␣in␣strings"));
          break;
        default:        ▷ high-bit character handling ◁
          if ((eight_bits)(∗id_first) > °177) app_tok(quoted_char);
        }
        app_tok(∗id_first ++);  count −−;
      }
      app('}');  app_scrap(exp, maybe_math);
    }
```
This code is used in section 211.

216.   We do not make the TEX string into a scrap, because there is no telling what
the user will be putting into it; instead we leave it open, to be picked up by the next
scrap. If it comes at the end of a section, it will be made into a scrap when *finish_C*
is called.

There's a known bug here, in cases where an adjacent scrap is *prelangle* or *prerangle*.
Then the TEX string can disappear when the \langle or \rangle becomes < or >. For
example, if the user writes |x<@ty@>|, the TEX string \hbox{y} eventually becomes
part of an *insert* scrap, which is combined with a *prelangle* scrap and eventually lost.
The best way to work around this bug is probably to enclose the @t...@> in @[...@]
so that the TEX string is treated as an expression.

⟨ Append a TEX string, without forming a scrap 216 ⟩ ≡
```
    app_str("\\hbox{");
    while (id_first < id_loc) {
      if ((eight_bits)(∗id_first) > °177) app_tok(quoted_char);
      else if (∗id_first ≡ '@') id_first ++;
      app_tok(∗id_first ++);
    }
    app('}');
```
This code is used in section 211.

---

217. The function *app_cur_id* appends the current identifier to the token list; it also builds a new scrap if *scrapping* ≡ *true*.

⟨ Predeclaration of procedures 8 ⟩ +≡
  static void *app_cur_id*(**boolean**);
  static text_pointer *C_translate*(**void**);
  static void *outer_parse*(**void**);

218.   **static void** *app_cur_id*(**boolean** *scrapping*)
    ▷ are we making this into a scrap? ◁
  {
    name_pointer $p \leftarrow$ *id_lookup*(*id_first*, *id_loc*, *normal*);
    if (p→*ilk* ≤ *custom*) {   ▷ not a reserved word ◁
      app(*id_flag* + (**int**)(p − *name_dir*));
      if (*scrapping*) *app_scrap*(p→*ilk* ≡ *func_template* ? *ftemplate* : *exp*,
          p→*ilk* ≡ *custom* ? *yes_math* : *maybe_math*);
    }
    else {
      app(*res_flag* + (**int**)(p − *name_dir*));
      if (*scrapping*) {
        if (p→*ilk* ≡ *alfop*) *app_scrap*(*ubinop*, *yes_math*);
        else *app_scrap*(p→*ilk*, *maybe_math*);
      }
    }
    ⟨ Flag the usage of this identifier, for the mini-index 312 ⟩
  }

219. When the '|' that introduces C text is sensed, a call on *C_translate* will return a pointer to the TEX translation of that text. If scraps exist in *scrap_info*, they are unaffected by this translation process.

  static text_pointer *C_translate*(**void**)
  {
    text_pointer *p*;   ▷ points to the translation ◁
    scrap_pointer *save_base* ← *scrap_base*;   ▷ holds original value of *scrap_base* ◁
    scrap_base ← *scrap_ptr* + 1; *C_parse*(*section_name*);   ▷ get the scraps together ◁
    if (*next_control* ≠ '|') *err_print*(␣("!␣Missing␣'|'␣after␣C␣text"));
    app_tok(*cancel*); *app_scrap*(*insert*, *maybe_math*);
    ▷ place a *cancel* token as a final "comment" ◁
    p ← *translate*();   ▷ make the translation ◁
    if (*scrap_ptr* > *max_scr_ptr*) *max_scr_ptr* ← *scrap_ptr*;
    scrap_ptr ← *scrap_base* − 1; *scrap_base* ← *save_base*;   ▷ scrap the scraps ◁
    return *p*;
  }

220.   The *outer_parse* routine is to *C_parse* as *outer_xref* is to *C_xref*: It constructs a sequence of scraps for C text until $next\_control \geq format\_code$. Thus, it takes care of embedded comments.

The token list created from within '| . . . |' brackets is output as an argument to \PB. Although ctwimac ignores \PB, other macro packages might use it to localize the special meaning of the macros that mark up program text.

222. Output of tokens.   So far our programs have only built up multi-layered
token lists in `CWEAVE`'s internal memory; we have to figure out how to get them into
the desired final form. The job of converting token lists to characters in the TEX
output file is not difficult, although it is an implicitly recursive process. Four main
considerations had to be kept in mind when this part of `CWEAVE` was designed. (a)
There are two modes of output: *outer* mode, which translates tokens like *force* into
line-breaking control sequences, and *inner* mode, which ignores them except that
blank spaces take the place of line breaks. (b) The *cancel* instruction applies to
adjacent token or tokens that are output, and this cuts across levels of recursion since
'*cancel*' occurs at the beginning or end of a token list on one level. (c) The TEX
output file will be semi-readable if line breaks are inserted after the result of tokens
like *break_space* and *force*. (d) The final line break should be suppressed, and there
should be no *force* token output immediately after '\Y\B'.

---

223. The output process uses a stack to keep track of what is going on at different "levels" as the token lists are being written out. Entries on this stack have three parts:

> *end_field* is the *tok_mem* location where the token list of a particular level will end;

> *tok_field* is the *tok_mem* location from which the next token on a particular level will be read;

> *mode_field* is the current mode, either *inner* or *outer*.

The current values of these quantities are referred to quite frequently, so they are stored in a separate place instead of in the *stack* array. We call the current values *cur_end*, *cur_tok*, and *cur_mode*.

The global variable *stack_ptr* tells how many levels of output are currently in progress. The end of output occurs when an *end_translation* token is found, so the stack is never empty except when we first begin the output process.

#define *inner* *false*   ▷ value of *mode* for C texts within TeX texts ◁
#define *outer* *true*   ▷ value of *mode* for C texts in sections ◁

⟨ Typedef declarations 22 ⟩ +≡
   typedef int mode;
   typedef struct {
      token_pointer *end_field*;   ▷ ending location of token list ◁
      token_pointer *tok_field*;   ▷ present location within token list ◁
      boolean *mode_field*;   ▷ interpretation of control tokens ◁
   } **output_state**;
   typedef output_state ∗stack_pointer;

224.   **#define** *stack_size* 2000   ▷ number of simultaneous output levels ◁
#define *cur_end* *cur_state.end_field*   ▷ current ending location in *tok_mem* ◁
#define *cur_tok* *cur_state.tok_field*   ▷ location of next output token in *tok_mem* ◁
#define *cur_mode* *cur_state.mode_field*   ▷ current mode of interpretation ◁
#define *init_stack* *stack_ptr* ← *stack*; *cur_mode* ← *outer*   ▷ initialize the stack ◁

⟨ Private variables 23 ⟩ +≡
   static output_state *cur_state*;   ▷ *cur_end*, *cur_tok*, *cur_mode* ◁
   static output_state *stack*[*stack_size*];   ▷ info for non-current levels ◁
   static stack_pointer *stack_end* ← *stack* + *stack_size* − 1;   ▷ end of *stack* ◁
   static stack_pointer *stack_ptr*;   ▷ first unused location in the output state stack ◁
   static stack_pointer *max_stack_ptr*;   ▷ largest value assumed by *stack_ptr* ◁

225.   ⟨ Set initial values 24 ⟩ +≡
   max_stack_ptr ← *stack*;

226. To insert token-list *p* into the output, the *push_level* subroutine is called; it saves the old level of output and gets a new one going. The value of *cur_mode* is not changed.

⟨ Predeclaration of procedures 8 ⟩ +≡
   static void *push_level*(**text_pointer**);
   static void *pop_level*(**void**);

227.   **static void** *push_level*(▷ suspends the current level ◁
      text_pointer *p*)
{
    if (*stack_ptr* ≡ *stack_end*) *overflow*(_("stack"));
    if (*stack_ptr* > *stack*) {   ▷ save current state ◁
       stack_ptr→*end_field* ← *cur_end*; *stack_ptr*→*tok_field* ← *cur_tok*;
       stack_ptr→*mode_field* ← *cur_mode*;
    }
    stack_ptr ++;
    if (*stack_ptr* > *max_stack_ptr*) *max_stack_ptr* ← *stack_ptr*;
    cur_tok ← *∗p*; *cur_end* ← *∗(p + 1)*;
}

228.   Conversely, the *pop_level* routine restores the conditions that were in force
when the current level was begun.

  This subroutine will never be called when *stack_ptr* ≡ 1.

  static void *pop_level*(**void**)
  {
      cur_end ← (−− *stack_ptr*)→*end_field*; *cur_tok* ← *stack_ptr*→*tok_field*;
      cur_mode ← *stack_ptr*→*mode_field*;
  }

229.   The *get_output* function returns the next byte of output that is not a reference
to a token list. It returns the values *identifier* or *res_word* or *section_code* if the next
token is to be an identifier (typeset in italics), a reserved word (typeset in boldface), or
a section name (typeset by a complex routine that might generate additional levels of
output). In these cases *cur_name* points to the identifier or section name in question.

⟨ Private variables 23 ⟩ +≡
  static name_pointer *cur_name*;

230.   #**define** *res_word* ⁰201   ▷ returned by *get_output* for reserved words ◁

       }
     }
     return (**eight_bits**) *a*;
   }

232.   The real work associated with token output is done by *make_output*. This procedure appends an *end_translation* token to the current token list, and then it repeatedly calls *get_output* and feeds characters to the output buffer until reaching the *end_translation* sentinel. It is possible for *make_output* to be called recursively, since a section name may include embedded C text; however, the depth of recursion never exceeds one level, since section names cannot be inside of section names.

   A procedure called *output_C* does the scanning, translation, and output of C text within '| ... |' brackets, and this procedure uses *make_output* to output the current token list. Thus, the recursive call of *make_output* actually occurs when *make_output* calls *output_C* while outputting the name of a section.

   static void *output_C* (**void**)   ▷ outputs the current token list ◁
   {

      else if (*a* ≡ *outdent*) *c*−−;
      else if (*a* ≡ *opt*) *a* ← *get_output*( );
      else if (*a* > *b*) *b* ← *a*;   ▷ if *a* ≡ ′␣′ we have *a* < *b* ◁
    }
  }
This code is used in section 236.

238. ⟨Output saved *indent* or *outdent* tokens 238⟩ ≡
   for (; $c > 0$; c−−) *out_str*("\\1");
   for (; $c < 0$; c++) *out_str*("\\2");

This code is used in sections 234 and 237.

239. The remaining part of *make_output* is somewhat more complicated. When we output a section name, we may need to enter the parsing and translation routines, since the name may contain C code embedded in | . . . | constructions. This C code is placed at the end of the active input buffer and the translation process uses the end of the active *tok_mem* area.

⟨Output a section name 239⟩ ≡
   out_str("\\X"); *cur_xref* ← (**xref_pointer**) *cur_name*→*xref*;

244. Phase two processing. We have assembled enough pieces of the puzzle in order to be ready to specify the processing in `CWEAVE`'s main pass over the source file. Phase two is analogous to phase one, except that more work is involved because we must actually output the TEX material instead of merely looking at the `CWEB` specifications.

static void *phase_two*(**void**)
{ *phase* ← 2; *reset_input*( );
  if (*show_progress*) *fputs*($\lrcorner$("\nWriting$\lrcorner$the$\lrcorner$output$\lrcorner$file..."), *stdout*);

  while (¬*input_has_ended*) ⟨Translate the current section 247⟩
}

245. ⟨Predeclaration of procedures 8⟩ +≡ **static void** *phase_two*(**void**);

246. The output file will contain the control sequence \Y between non-null sections of a section, e.g., between the TEX and definition parts if both are nonempty. This puts a little white space between the parts when they are printed. However, we don't want \Y to occur between two definitions within a single section. The variables *out_line* or *out_ptr* will change if a section is non-null, so the following macros '*save_position*' and '*emit_space_if_needed*' are able to handle the situation:

#**define** *save_position* *save_line* ← *out_line*; *save_place* ← *out_ptr*
#**define** *emit_space_if_needed*
        if (*save_line* ≠ *out_line* ∨ *save_place* ≠ *out_ptr*) *out_str*("\\Y");
        space_checked ← *true*;

>   *check_complete*();   ▷ was all of the change file used? ◁
> }

265. ⟨Predeclaration of procedures 8⟩ +≡ **static void** *phase_three*(**void**);

266. Just before the index comes a list of all the changed sections, including the index section itself—NOT!

267. No need to tell about changed sections.

268. A left-to-right radix sorting method is used, since this makes it easy to adjust the collating sequence and since the running time will be at worst proportional to the total length of all entries in the index. We put the identifiers into different lists based on their first characters. (Uppercase letters are put into the same list as the corresponding lowercase letters, since we want to have '$t < TeX < $ **to**'.) The list for character c begins at location $bucket[c]$ and continues through the $blink$ array.

⟨ Private variables 23 ⟩ +≡
  static name_pointer $bucket[256]$;
  static name_pointer $next\_name$;   ▷ successor of cur_name when sorting ◁
  static name_pointer $blink[max\_names]$;   ▷ links in the buckets ◁

269. To begin the sorting, we go through all the hash lists and put each entry having a nonempty cross-reference list into the proper bucket.

⟨ Do the first pass of sorting 269 ⟩ ≡
  {
    int c;
    for $(c \leftarrow 0;\ c < 256;\ c\texttt{++})\ bucket[c] \leftarrow \Lambda$;
    for $(h \leftarrow hash;\ h \leq hash\_end;\ h\texttt{++})$ {
      $next\_name \leftarrow *h$;
      while $(next\_name)$ {
        $cur\_name \leftarrow next\_name;\ next\_name \leftarrow cur\_name\text{→}link$;
        if $(cur\_name\text{→}xref \neq (\textbf{void}\ *)\ xmem)$ {
          $c \leftarrow (cur\_name\text{→}byte\_start)[0]$;
          if $(xisupper(c))\ c \leftarrow tolower(c)$;
          $blink[cur\_name - name\_dir] \leftarrow bucket[c];\ bucket[c] \leftarrow cur\_name$;
        }
      }
    }
  }
This code is used in section 264.

270. During the sorting phase we shall use the *cat* and *trans* arrays from CWEAVE's parsing algorithm and rename them *depth* and *head*. They now represent a stack of identifier lists for all the index entries that have not yet been output. The variable *sort_ptr* tells how many such lists are present; the lists are output in reverse order (first *sort_ptr*, then *sort_ptr* − 1, etc.). The jth list starts at *head*[j], and if the first k characters of all entries on this list are known to be equal we have $depth[j] \equiv k$.

⟨ Rest of *trans_plus* union 270 ⟩ ≡
  name_pointer *Head*;

This code is used in section 126.

271. #**define** *depth* *cat*   ▷ reclaims memory that is no longer needed for parsing ◁
#**define** *head* *trans_plus*.*Head*   ▷ ditto ◁
  format *sort_pointer* *int*

}
```

288.   Mogrify CWEAVE **into** CTWILL.   Here is a sort of user manual for CTWILL—
which is exactly like CWEAVE except that it produces much better documentation, for
which you must work harder. As with CWEAVE, input comes from a source file `foo.w`
and from an optional (but now almost mandatory) change file `foo.ch`; output goes
to `foo.tex`, `foo.idx`, and `foo.scn`. Unlike CWEAVE, there is an additional output
file, `foo.aux`, which records all nonexternal definitions. The `.aux` file also serves as
an input file on subsequent runs. You should run CTWILL twice, once to prime the
pump and once to get decent answers.

Moreover, you must run the output twice through TEX. (This double duplicity
suggested the original name TWILL.) After '`tex foo`' you will have output that looks
like final pages except that the entries of mini-indexes won't be alphabetized. TEX
will say 'This is the first pass', and it will produce a weird file called `foo.ref`. Say

$$\text{refsort < foo.ref > foo.sref}$$

and then another '`tex foo`' will produce alphabetized output. While TEX runs it
emits messages filled with numeric data, indicating how much space is consumed by
each program section. If you can decipher these numbers (see `ctwimac.tex`), you can
use them to fine-tune the page layout. You might be tempted to do fine tuning by
editing `foo.tex` directly, but it's better to incorporate all changes into `foo.ch`.

The mini-indexes list identifiers that are used but not defined on each two-page
spread. At the end of each section, CTWILL gives TEX a list of identifiers used in that
section and information about where they are defined. The macros in `ctwimac.tex`
figure out which identifiers should go in each mini-index, based on how the pages
break. (Yes, those macros are pretty hairy.)

The information that CTWILL concocts from `foo.w` is not always correct. Sometimes
you'll use an identifier that you don't want indexed; for example, your exposition
might talk about $f(x)$ when you don't mean to refer to program variables f or x.
Sometimes you'll use an identifier that's defined in a header file, unknown to CTWILL.
Sometimes you'll define a single identifier in several different places, and CTWILL won't
know which definition to choose. But all is not lost. CTWILL guesses right most of the
time, and you can give it the necessary hints in other places via your change file.

If you think it's easy to write a completely automatic system that doesn't make
CTWILL's mistakes and doesn't depend so much on change files, please do so.

CTWILL uses a very simple method to generate mini-index info. By understanding
this method, you will understand how to fix it when things go wrong. Every identifier
has a current "meaning," consisting of its abstract type and the number of the section
in which it was most recently defined. For example, if your C program says '**char** $*s$'
in section 3, the meaning of s gets changed to '**char** $*$, §3' while CTWILL is processing
that section. If you refer to s in section 10, and if s hasn't been redefined in the
meantime, and if section 10 doesn't wind up on the same two-page spread as section 3,
the mini-index generated by section 10 will say "s: **char** $*$, §3."

289.   The current meaning of every identifier is initially '`\uninitialized`'. Then
`CTWILL` reads the `.aux` file for your job, if any; this `.aux` file contains all definitions
of new meanings in the previous run, so it tells `CTWILL` about definitions that will be
occurring in the future. If all identifiers have a unique definition, they will have a
unique and appropriate meaning in the mini-indexes.

But some identifiers, like parameters to procedures, may be defined several times.
Others may not be defined at all, because they are defined elsewhere and mentioned in
header files included by the C preprocessor. To solve this problem, `CTWILL` provides
mechanisms by which the current meaning of an identifier can be temporarily or
permanently changed.

For example, the operation

$$\texttt{@\$s \{FOO\}3 \textbackslash\&\{char\} \$*\$@>}$$

changes the current meaning of *s* to the TEX output of '`\&{char} $*$`' in section 3 of
program FOO. All entries in the `.aux` file are expressed in the form of this `@$` operator;
therefore you can use a text editor to paste such entries into a `.ch` file, whenever you
want to tell `CTWILL` about definitions that are out of order or from other programs.

Before reading the `.aux` file, `CTWILL` actually looks for a file called `system.bux`,
which will be read if present. And after `foo.aux`, a third possibility is `foo.bux`.
The general convention is to put definitions of system procedures such as *printf*
into `system.bux`, and to put definitions found in specifically foo-ish header files into
`foo.bux`. Like the `.aux` files, `.bux` files should contain only `@$` specifications; this
rule corresponds to the fact that 'bux' is the plural of '$'. The `.bux` files may also
contain `@i` includes.

A companion operation `@%` signifies that all `@$` specifications from the present
point to the beginning of the next section will define *temporary* meanings instead of
permanent ones. Temporary meanings are placed into the mini-index of the current
section; the permanent (current) meaning of the identifier will not be changed, nor
will it appear in the mini-index of the section. If several temporary meanings are
assigned to the same identifier in a section, all will appear in the mini-index. Each
`@%` toggles the temporary/permanent convention; thus, after an even number of `@%`
operations in a section, meanings specified by `@$` are permanent.

The operation `@-` followed by an identifier followed by `@>` specifies that the identifier
should not generate a mini-index entry in the current section (unless, of course, a
temporary meaning is assigned).

If `@-foo@>` appears in a section where a new permanent meaning is later defined
by the semantics of C, the current meaning of *foo* will not be redefined; moreover,
this current meaning, which may have been changed by `@$foo ...@>`, will also be
written to the `.aux` file. Therefore you can control what `CTWILL` outputs; you can
keep it from repeatedly contaminating the `.aux` file with things you don't like.

The meaning specified by `@$...@>` generally has four components: an identifier
(followed by space), a program name (enclosed in braces), a section number (followed
by space), and a TEX part. The TEX part must have fewer than 50 characters.

#**define** *max_tex_chars* 50   ▷ limit on the TEX part of a meaning ◁

290.   If the TeX part starts with '=', the mini-index entry will contain an equals sign instead of a colon; for example,

@$buf_size {PROG}10 =\T{200}@>

generates either '*buf_size* = 200, §10' or '*buf_size* = 200, PROG §10', depending on whether 'PROG' is or isn't the title of the current program. If the TeX part is '\zip', the mini-index entry will contain neither colon nor equals, just a comma. The program name and section number can also be replaced by a string. For example,

@$printf "<stdio.h>" \zip@>

will generate a mini-index entry like '*printf*, <stdio.h>.'.

A special "proofmode" is provided so that you can check CTWILL's conclusions about cross-references. Run CTWILL with the flag +P, and TeX will produce a specially formatted document (*without* mini-indexes) in which you can check that your specifications are correct. You should always do this before generating mini-indexes, because mini-indexes can mask errors if page breaks are favorable but the errors might reveal themselves later after your program has changed. The proofmode output is much easier to check than the mini-indexes themselves.

The control code @r or @R causes CTWILL to emit the TeX macro '\shortpage' just before starting the next section of the program. This causes the section to appear at the top of a right-hand page, if it would ordinarily have appeared near the bottom of a left-hand page and split across the pages. (The \shortpage macro is fragile and should be used only in cases where it will not mess up the output; insert it only when fine-tuning a set of pages.) If the next section is a starred section, the behavior is slightly different (but still fragile): The starred section will either be postponed to a left-hand page, if it normally would begin on a right-hand page, or vice versa. In other words, @r@* inverts the left/right logic.

CTANGLE does not recognize the operations @$, @%, @-, and @r, which are unique to CTWILL. But that is no problem, since you use them only in change files set up for book publishing, which are quite different from the change files you set up for tangling.

(End of user manual.)

291. Temporary and permanent meanings. CTWILL has special data structures to keep track of current and temporary meanings. These structures were not designed for maximum efficiency; they were designed to be easily grafted into CWEAVE's existing code without major surgery.

#**define** *max_meanings* 100   ▷ max temporary meanings per section ◁
#**define** *max_titles* 100   ▷ max distinct program or header names in meanings ◁

⟨ Typedef declarations 22 ⟩ +≡

      case '[': *app_str*("[\\,]"); **goto** *catch14*;
      }
    for (*j* ← ∗*p*; *j* < ∗(*p* + 1); *j*++)
      if (∗*j* < *tok_flag*) {
        if (∗*j* ≡ *inserted*) **break**;
        if (*j* ≡ *tok_loc*) *ident_seen* ← *true*;
        else *app*(∗*j*);
      }
      else if (∗*j* ≥ *inner_tok_flag*) *confusion*(_("inner"));
      else if (*app_supp*(∗*j* − *tok_flag* + *tok_start*)) **goto** *catch14*;
    return *false*;
  catch14: **return** ∗(∗(*p* + 1) − 1) ≡ '9';   ▷ was production 14 used? ◁
  }

301. ⟨Predeclaration of procedures 8⟩ +≡ **static boolean** *app_supp*(**text_pointer**);

302.   The trickiest part of `CTWILL` is the procedure *make_ministring*$(pp + l)$, with offset $l \in \{0, 1, 2\}$, which tries to figure out a symbolic form of definition after *make_underlined*$(pp + l)$ has been called. We rely heavily on the existing productions, which force the translated texts to have a structure that's decodable even though the underlying *cat* and *mathness* codes have disappeared.

320. Extensions to CWEB.   The following sections introduce new or improved features that have been created by numerous contributors over the course of a quarter century.

limit: **char** ∗, COMMON.W §22.
loc: **char** ∗, COMMON.W §22.
memcpy, <string.h>.
strlen, <string.h>.

tex_file_name: **char** [],
     COMMON.W §73.
title_code: **static**
     name_pointer [], §292.

title_code_ptr: **static**
     name_pointer ∗, §292.
title_lookup: **static**
     sixteen_bits ( ), §317.

321. **Formatting alternatives.** CWEAVE indents declarations after old-style function definitions and long parameter lists of modern function definitions. With the -i option they will come out flush left.

#**define** *indent_param_decl* *flags*['i']
▷ should formal parameter declarations be indented? ◁

⟨ Set initial values 24 ⟩ +≡
  indent_param_decl ← *true*;

322. The original manual described the -o option for CWEAVE, but this was not yet present. Here is a simple implementation. The purpose is to suppress the extra space between local variable declarations and the first statement in a function block.

#**define** *order_decl_stmt* *flags*['o'] ▷ should declarations and statements be separated? ◁

⟨ Set initial values 24 ⟩ +≡
  order_decl_stmt ← *true*;

323. Output file update. Most C projects are controlled by a `Makefile` that automatically takes care of the temporal dependecies between the different source modules. It may be convenient that `CWEB` doesn't create new output for all existing files, when there are only changes to some of them. Thus the `make` process will only recompile those modules where necessary. You can activate this feature with the '`+c`' command-line option. The idea and basic implementation of this mechanism can be found in the program `NUWEB` by Preston Briggs, to whom credit is due.

⟨ Update the result when it has changed 323 ⟩ ≡
  {
    if $((tex\_file \leftarrow fopen(tex\_file\_name, \texttt{"r"})) \neq \Lambda)$ {
      boolean $comparison \leftarrow false$;
      if $((check\_file \leftarrow fopen(check\_file\_name, \texttt{"r"})) \equiv \Lambda)$
        $fatal(\_(\texttt{"!}\_\texttt{Cannot}\_\texttt{open}\_\texttt{output}\_\texttt{file}\_\texttt{"}), check\_file\_name)$;
      ⟨ Compare the temporary output to the previous output 324 ⟩
      $fclose(tex\_file)$; $tex\_file \leftarrow \Lambda$; $fclose(check\_file)$; $check\_file \leftarrow \Lambda$;
      ⟨ Take appropriate action depending on the comparison 325 ⟩
    }
    else $rename(check\_file\_name, tex\_file\_name)$;   ▷ This was the first run ◁
    $strcpy(check\_file\_name, \texttt{""})$;   ▷ We want to get rid of the temporary file ◁
  }

This code is used in section 264.

324. We hope that this runs fast on most systems.

⟨ Compare the temporary output to the previous output 324 ⟩ ≡
  do {
    char $x[\texttt{BUFSIZ}]$, $y[\texttt{BUFSIZ}]$;
    int $x\_size \leftarrow fread(x, \textbf{sizeof}(\textbf{char}), \texttt{BUFSIZ}, tex\_file)$;
    int $y\_size \leftarrow fread(y, \textbf{sizeof}(\textbf{char}), \texttt{BUFSIZ}, check\_file)$;

    $comparison \leftarrow (x\_size \equiv y\_size) \wedge \neg memcmp(x, y, x\_size)$;
  } **while** $(comparison \wedge \neg feof(tex\_file) \wedge \neg feof(check\_file))$;

This code is used in section 323.

325. Note the superfluous call to *remove* before *rename*. We're using it to get around a bug in some implementations of *rename*.

⟨ Take appropriate action depending on the comparison 325 ⟩ ≡
  if $(comparison)$ $remove(check\_file\_name)$;   ▷ The output remains untouched ◁
  else {
    $remove(tex\_file\_name)$; $rename(check\_file\_name, tex\_file\_name)$;
  }
