The MFT processor

(Version 2.1, January 2021)

1* Introduction.   This program converts a METAFONT or METAPOST source file to a TEX file. It was written by D. E. Knuth in June, 1985; a somewhat similar SAIL program had been developed in January, 1980. Changes for METAPOST by W. Bzyl in July, 2001.

The general idea is to input a file called, say, `foo.mf` and to produce an output file called, say, `foo.tex`. The latter file, when processed by TEX, will yield a "prettyprinted" representation of the input file.

Line breaks in the input are carried over into the output; moreover, blank spaces at the beginning of a line are converted to quads of indentation in the output. Thus, the user has full control over the indentation and line breaks. Each line of input is translated independently of the others.

A slight change to METAFONT's comment convention allows further control. Namely, '`%%`' indicates that the remainder of an input line should be copied verbatim to the output; this interrupts the translation and forces MFT to produce a certain result.

Furthermore, '`%%%` ⟨token₁⟩...⟨tokenₙ⟩' introduces a change in MFT's formatting rules; all tokens after the first will henceforth be translated according to the current conventions for ⟨token₁⟩. The tokens must be symbolic (i.e., not numeric or string tokens). For example, the input line

<div align="center">

`%%% addto fill draw filldraw`

</div>

says that the '`fill`', '`draw`', and '`filldraw`' operations of plain METAFONT should be formatted as the primitive token '`addto`', i.e., in boldface type. (Without such reformatting commands, MFT would treat '`fill`' like an ordinary tag or variable name. In fact, you need a reformatting command even to get parentheses to act like delimiters!)

METAFONT comments, which follow a single `%` sign, should be valid TEX input. But METAFONT material can be included in `|...|` within a comment; this will be translated by MFT as if it were not in a comment. For example, a phrase like '`make |x2r| zero`' will be translated into '`make $x_{2r}$ zero`'.

The rules just stated apply to lines that contain one, two, or three `%` signs in a row. Comments to MFT can follow '`%%%%`'. Five or more `%` signs should not be used.

Beside the normal input file, MFT also looks for a change file (e.g., '`foo.ch`'), which allows substitutions to be made in the translation. The change file follows the conventions of WEB, and it should be null if there are no changes. (Changes usually contain verbatim instructions to compensate for the fact that MFT cannot format everything in an optimum way.)

There's also a third input file (e.g., '`plain.mft`'), which is input before the other two. This file normally contains the '`%%%`' formatting commands that are necessary to tune MFT to a particular style of METAFONT code, so it is called the style file.

The output of MFT should be accompanied by the macros in a small package called `mftmac.tex`.

Caveat: This program is not as "bulletproof" as the other routines produced by Stanford's TEX project. It takes care of a great deal of tedious formatting, but it can produce strange output, because METAFONT is an extremely general language. Users should proofread their output carefully.

2* MFT uses a few features of the local Pascal compiler that may need to be changed in other installations:

1) Case statements have a default.
2) Input-output routines may need to be adapted for use with a particular character set and/or for printing messages on the user's terminal.

These features are also present in the Pascal version of TEX, where they are used in a similar (but more complex) way. System-dependent portions of MFT can be identified by looking at the entries for 'system dependencies' in the index below.

The "banner line" defined here should be changed whenever MFT is modified.

define *my_name* ≡ ´mft´
define *banner* ≡ ´This␣is␣MFT,␣Version␣2.1´

3* The program begins with a fairly normal header, made up of pieces that will mostly be filled in later. The MF input comes from files *mf_file*, *change_file*, and *style_file*; the TEX output goes to file *tex_file*.

  If it is necessary to abort the job because of a fatal error, the program calls the '*jump_out*' procedure.

  define *class* ≡ *class_var*

⟨Compiler directives 4⟩
program *MFT*(*mf_file*, *change_file*, *style_file*, *tex_file*);
  const ⟨Constants in the outer block 8*⟩
  type ⟨Types in the outer block 12⟩
  var ⟨Globals in the outer block 9⟩
    ⟨Error handling procedures 29⟩
    ⟨Define *parse_arguments* 115*⟩
  procedure *initialize*;
    var ⟨Local variables for initialization 14⟩
    begin *kpse_set_program_name*(*argv*[0], *my_name*); *parse_arguments*; ⟨Set initial values 10⟩;
    end;

8* The following parameters are set big enough to handle the Computer Modern fonts, so they should be sufficient for most applications of MFT.

⟨Constants in the outer block 8*⟩ ≡
  max_bytes = 60000;   { the number of bytes in tokens; must be less than 65536 }
  max_names = 6000;   { number of tokens }
  hash_size = 353;   { should be prime }
  buf_size = 3000;   { maximum length of input line }
  line_length = 79;   { lines of TEX output have at most this many characters, should be less than 256 }
This code is used in section 3*.

13* The original Pascal compiler was designed in the late 60s, when six-bit character sets were common, so it did not make provision for lowercase letters. Nowadays, of course, we need to deal with both capital and small letters in a convenient way, especially in a program for font design; so the present specification of MFT has been written under the assumption that the Pascal compiler and run-time system permit the use of text files with more than 64 distinguishable characters. More precisely, we assume that the character set contains at least the letters and symbols associated with ASCII codes ´40 through ´176. If additional characters are present, MFT can be configured to work with them too.

Since we are dealing with more characters than were present in the first Pascal compilers, we have to decide what to call the associated data type. Some Pascals use the original name *char* for the characters in text files, even though there now are more than 64 such characters, while other Pascals consider *char* to be a 64-element subrange of a larger data type that has some other name.

In order to accommodate this difference, we shall use the name *text_char* to stand for the data type of the characters that are converted to and from *ASCII_code* when they are input and output. We shall also assume that *text_char* consists of the elements *chr*(*first_text_char*) through *chr*(*last_text_char*), inclusive. The following definitions should be adjusted if necessary.

> **define** *text_char* ≡ *ASCII_code*   { the data type of characters in text files }
> **define** *first_text_char* = 0   { ordinal number of the smallest element of *text_char* }
> **define** *last_text_char* = 255   { ordinal number of the largest element of *text_char* }

⟨ Types in the outer block 12 ⟩ +≡
    text_file = **packed file of** *text_char*;

17* The ASCII code is "standard" only to a certain extent, since many computer installations have found it advantageous to have ready access to more than 94 printing characters. If MFT is being used on a garden-variety Pascal for which only standard ASCII codes will appear in the input and output files, it doesn't really matter what codes are specified in *xchr*[0 .. ´37], but the safest policy is to blank everything out by using the code shown below.

However, other settings of *xchr* will make MFT more friendly on computers that have an extended character set, so that users can type things like '≠' instead of '<>', and so that MFT can echo the page breaks found in its input. People with extended character sets can assign codes arbitrarily, giving an *xchr* equivalent to whatever characters the users of MFT are allowed to have in their input files. Appropriate changes to MFT's *char_class* table should then be made. (Unlike TEX, each installation of METAFONT has a fixed assignment of category codes, called the *char_class*.) Such changes make portability of programs more difficult, so they should be introduced cautiously if at all.

⟨ Set initial values 10 ⟩ +≡
    for *i* ← 1 **to** ´37 **do** *xchr*[*i*] ← *chr*(*i*);
    for *i* ← ´177 **to** ´377 **do** *xchr*[*i*] ← *chr*(*i*);

20* Terminal output is done by writing on file *term_out*, which is assumed to consist of characters of type *text_char*:

> **define** *term_out* ≡ *stdout*
> **define** *print*(#) ≡ *write*(*term_out*, #)   {'*print*' means write on the terminal}
> **define** *print_ln*(#) ≡ *write_ln*(*term_out*, #)   {'*print*' and then start new line}
> **define** *new_line* ≡ *write_ln*(*term_out*)   {start new line on the terminal}
> **define** *print_nl*(#) ≡   {print information starting on a new line}
>   **begin** *new_line*; *print*(#);
>   **end**

21* Different systems have different ways of specifying that the output on a certain file will appear on the user's terminal.

⟨Set initial values 10⟩ +≡
    {nothing need be done}

22* The *update_terminal* procedure is called when we want to make sure that everything we have output to the terminal so far has actually left the computer's internal buffers and been sent.

> **define** *update_terminal* ≡ *fflush*(*term_out*)   {empty the terminal output buffer}

24* The following code opens the input files.

procedure *open_input*;   {prepare to read inputs}
  begin if *metapost* **then** *mf_file* ← *kpse_open_file*(*cmdline*(*optind*), *kpse_mp_format*)
  else *mf_file* ← *kpse_open_file*(*cmdline*(*optind*), *kpse_mf_format*);
  if *change_name* **then**
    begin if *metapost* **then** *change_file* ← *kpse_open_file*(*change_name*, *kpse_mp_format*)
    else *change_file* ← *kpse_open_file*(*change_name*, *kpse_mf_format*);
    end;
  style_file ← *kpse_open_file*(*style_name*[0], *kpse_mft_format*); *i_style_name* ← 1;
  end;

26* The following code opens *tex_file*. Since this file was listed in the program header, we assume that the Pascal runtime system has checked that a suitable external file name has been given.

⟨Set initial values 10⟩ +≡
  rewrite(*tex_file*, *tex_name*);

28* The *input_ln* procedure brings the next line of input from the specified file into the *buffer* array and returns the value *true*, unless the file has already been entirely read, in which case it returns *false*. The conventions of TeX are followed; i.e., *ASCII_code* numbers representing the next line of the file are input into *buffer*[0], *buffer*[1], ..., *buffer*[*limit* − 1]; trailing blanks are ignored; and the global variable *limit* is set to the length of the line. The value of *limit* must be strictly less than *buf_size*.

function *input_ln*(**var** *f* : *text_file*): *boolean*;   { inputs a line or returns *false* }
   var *final_limit*: 0 . . *buf_size*;   { *limit* without trailing blanks }
   begin *limit* ← 0; *final_limit* ← 0;
   if *eof*(*f*) **then** *input_ln* ← *false*
   else begin while ¬*eoln*(*f*) **do**
         begin *buffer*[*limit*] ← *xord*[*getc*(*f*)]; *incr*(*limit*);
         if *buffer*[*limit* − 1] ≠ "␣" **then** *final_limit* ← *limit*;
         if *limit* = *buf_size* **then**
            begin while ¬*eoln*(*f*) **do** *vgetc*(*f*);
            decr(*limit*);   { keep *buffer*[*buf_size*] empty }
            if *final_limit* > *limit* **then** *final_limit* ← *limit*;
            print_nl(´!␣Input␣line␣too␣long´); *loc* ← 0; *error*;
            end;
         end;
      read_ln(*f*); *limit* ← *final_limit*; *input_ln* ← *true*;
      end;
   end;

31*   The *jump_out* procedure cleans up, prints appropriate messages, and exits back to the operating
system.

  define *fatal_error*(#) ≡
          begin *new_line*; *print*(#); *error*; *mark_fatal*; *jump_out*;
          end

⟨ Error handling procedures 29 ⟩ +≡
procedure *jump_out*;
  begin   { here files should be closed if the operating system requires it }
  ⟨ Print the job *history* 113 ⟩;
  new_line;
  if (*history* ≠ *spotless*) ∧ (*history* ≠ *harmless_message*) **then** *uexit*(1)
  else *uexit*(0);
  end;

47* ⟨Read from *style_file* and maybe turn off *styling* 47*⟩ ≡

  begin *incr*(*line*);

  if ¬*input_ln*(*style_file*) **then**

    begin if *i_style_name* ≠ *n_style_name* **then**

      begin *xfclose*(*style_file*, *style_name*[*i_style_name* − 1]);

      style_file ← *kpse_open_file*(*style_name*[*i_style_name*], *kpse_mft_format*);

      i_style_name ← *i_style_name* + 1;

      end

    else begin *styling* ← *false*;

      end;

    line ← 0;

    end;

  end

This code is used in section 45.

63* Initializing the primitive tokens.   Each token read by MFT is recognized as belonging to one of the following "types":

  define $indentation = 0$ { internal code for space at beginning of a line }
  define $end\_of\_line = 1$ { internal code for hypothetical token at end of a line }
  define $end\_of\_file = 2$ { internal code for hypothetical token at end of the input }
  define $verbatim = 3$ { internal code for the token '`%%`' }
  define $set\_format = 4$ { internal code for the token '`%%%`' }
  define $mft\_comment = 5$ { internal code for the token '`%%%%`' }
  define $min\_action\_type = 6$ { smallest code for tokens that produce "real" output }
  define $numeric\_token = 6$ { internal code for tokens like '`3.14159`' }
  define $string\_token = 7$ { internal code for tokens like '`"pie"`' }
  define $min\_symbolic\_token = 8$ { smallest internal code for a symbolic token }
  define $op = 8$ { internal code for tokens like '`sqrt`' }
  define $command = 9$ { internal code for tokens like '`addto`' }
  define $endit = 10$ { internal code for tokens like '`fi`' }
  define $binary = 11$ { internal code for tokens like '`and`' }
  define $abinary = 12$ { internal code for tokens like '`+`' }
  define $bbinary = 13$ { internal code for tokens like '`step`' }
  define $ampersand = 14$ { internal code for the token '`&`' }
  define $pyth\_sub = 15$ { internal code for the token '`+-+`' }
  define $as\_is = 16$ { internal code for tokens like '`]`' }
  define $bold = 17$ { internal code for tokens like '`nullpen`' }
  define $type\_name = 18$ { internal code for tokens like '`numeric`' }
  define $path\_join = 19$ { internal code for the token '`..`' }
  define $colon = 20$ { internal code for the token '`:`' }
  define $semicolon = 21$ { internal code for the token '`;`' }
  define $backslash = 22$ { internal code for the token '`\`' }
  define $double\_back = 23$ { internal code for the token '`\\`' }
  define $less\_or\_equal = 24$ { internal code for the token '`<=`' }
  define $greater\_or\_equal = 25$ { internal code for the token '`>=`' }
  define $not\_equal = 26$ { internal code for the token '`<>`' }
  define $sharp = 27$ { internal code for the token '`#`' }
  define $comment = 28$ { internal code for the token '`%`' }
  define $recomment = 29$ { internal code used to resume a comment after '`|`…`|`' }
  define $min\_suffix = 30$ { smallest code for symbolic tokens in suffixes }
  define $internal = 30$ { internal code for tokens like '`pausing`' }
  define $input\_command = 31$ { internal code for tokens like '`input`' }
  define $btex\_code = 32$ { begin TEX material (`btex`) }
  define $verbatim\_code = 33$ { begin TEX material (`verbatimtex`) }
  define $etex\_marker = 34$ { end TEX material (`etex`) }
  define $special\_tag = 35$ { internal code for tags that take at most one subscript }
  define $tag = 36$ { internal code for nonprimitive tokens }
⟨ Assign the default value to $ilk[p]$ 63* ⟩ ≡
  $ilk[p] \leftarrow tag$

This code is used in section 62.

65*   We begin with primitives common to METAFONT and METAPOST.

The intended use of the macros above might not be immediately obvious, but the riddle is answered by the following:

⟨ Store all the primitives 65* ⟩ ≡
    $id\_loc \leftarrow 18$;
    $pr2$ (".")(".")($path\_join$);
    $pr1$ ("[")(as_is);
    $pr1$ ("]")(as_is);
    $pr1$ ("}")(as_is);
    $pr1$ ("{")(as_is);
    $pr1$ (":")($colon$);
    $pr2$ (":")(":")($colon$);
    $pr3$ ("|")("|")(":")($colon$);
    $pr2$ (":")("=")(as_is);
    $pr1$ (",")(as_is);
    $pr1$ (";")($semicolon$);
    $pr1$ ("\")($backslash$);
    $pr2$ ("\")("\")($double\_back$);
    $pr5$ ("a")("d")("d")("t")("o")($command$);
    $pr2$ ("a")("t")($bbinary$);
    $pr7$ ("a")("t")("l")("e")("a")("s")("t")(op);
    $pr10$ ("b")("e")("g")("i")("n")("g")("r")("o")("u")("p")($command$);
    $pr8$ ("c")("o")("n")("t")("r")("o")("l")("s")(op);
    $pr4$ ("c")("u")("l")("l")($command$);
    $pr4$ ("c")("u")("r")("l")(op);
    $pr10$ ("d")("e")("l")("i")("m")("i")("t")("e")("r")("s")($command$);
    $pr8$ ("e")("n")("d")("g")("r")("o")("u")("p")($endit$);
    $pr8$ ("e")("v")("e")("r")("y")("j")("o")("b")($command$);
    $pr6$ ("e")("x")("i")("t")("i")("f")($command$);
    $pr11$ ("e")("x")("p")("a")("n")("d")("a")("f")("t")("e")("r")($command$);

75* Inputting the next token.   MFT's lexical scanning routine is called *get_next*. This procedure inputs
the next token of METAFONT input and puts its encoded meaning into two global variables, *cur_type* and
cur_tok.

The **btex ... etex** and **verbatimtex ... etex** features need to be implemented at a low level in the
scanning process. This is implemented by changing the behavior of the scanner via *scanner_status* global
variable.

define *normal* = 0   { *scanner_status* at "quiet times" }
define *verbatimtex_flushing* = 1   { *scanner_status* when moving verbatim TEX material }
define *btex_flushing* = 2   { *scanner_status* when moving TEX code }

⟨ Globals in the outer block 9 ⟩ +≡
cur_type: *eight_bits*;   { type of token just scanned }
cur_tok: *integer*;   { hash table or buffer location }
prev_type: *eight_bits*;   { previous value of *cur_type* }
prev_tok: *integer*;   { previous value of *cur_tok* }
scanner_status: *normal .. btex_flushing*;   { are we scanning at high speed? }

79*   If changes are made to accommodate non-ASCII character sets, they should be essentially the same in
MFT as in METAFONT. However, MFT has an additional class number, the *end_line_class*, which is used only
for the special character *carriage_return* that is placed at the end of the input buffer.

define *carriage_return* = ´15   { special code placed in *buffer*[*limit*] }

This code is used in section 80.

88* MFT calls *flush_buffer*(*out_ptr*, *false*) before it has input anything. We initialize the output variables so that the first line of the output file will be '\input mftmac' or '\input mptmac' if a METAPOST file is converted.

⟨Set initial values 10⟩ +≡

 out_ptr ← 1; *out_buf*[1] ← "␣"; *out_line* ← 1;

 if *metapost* **then**

  begin *write*(*tex_file*, ´\input␣mptmac´);

  end

 else *write*(*tex_file*, ´\input␣mftmac´);

97*   Translation.   The main work of MFT is accomplished by a routine that translates the tokens, one by one, with a limited amount of lookahead/lookbehind. Automata theorists might loosely call this a "finite state transducer," because the flow of control is comparatively simple.

procedure *do_the_translation*;
 label *restart*, *reswitch*, *done*, *exit*;
 var *k*: 0 . . *buf_size*;   { looks ahead in the buffer }
  t: *integer*;   { type that spreads to new tokens }
 begin *restart*: **if** *out_ptr* > 0 **then** *flush_buffer*(*out_ptr*, *false*);
 empty_buffer ← *true*;
 loop begin *get_next*;

    and **goto** *reswitch* 110⟩;
  end_of_file: **return**;
  ⟨Cases that translate primitive tokens 100⟩
  comment, *recomment*: ⟨Translate a comment and **goto** *restart*, unless there's a |...| segment 108⟩;
  verbatim: ⟨Copy the rest of the current input line to the output, then **goto** *restart* 109⟩;
  set_format: ⟨Change the translation format of tokens, and **goto** *restart* or *reswitch* 111⟩;
  internal, *special_tag*, *tag*: ⟨Translate a tag and possible subscript 106⟩;
  end;   { all cases have been listed }
  end;
exit: **end**;

112*   The main program.   Let's put it all together now: MFT starts and ends here.

begin *initialize*;   { beginning of the main program }
print(*banner*);   { print a "banner line" }
print_ln(*version_string*); ⟨Store all the primitives 65*⟩;
⟨Store all the translations 73⟩;
⟨Initialize the input system 44⟩;
do_the_translation; ⟨Check that all changes have been read 49⟩;
⟨Print the job *history* 113⟩;
new_line;
if (*history* ≠ *spotless*) ∧ (*history* ≠ *harmless_message*) **then** *uexit*(1)
else *uexit*(0);
end.

114*   System-dependent changes.   The user calls MFT with arguments on the command line. These are either filenames or flags (beginning with '−'). The following globals are for communicating the user's desires to the rest of the program. The various *name* variables contain strings with the full names of those files, as UNIX knows them.

define $max\_style\_name = 32$

⟨ Globals in the outer block 9 ⟩ +≡
change_name, *tex_name*: *const_c_string*;
style_name: **array** $[0 \mathinner{.\,.} max\_style\_name - 1]$ **of** *const_c_string*;
n_style_name: *c_int_type*;   { Number of values in *style_name* array. }
i_style_name: *c_int_type*;   { The next *style_name*. }
metapost: *c_int_type*;   { *true* for METAPOST, *false* for METAFONT }

115* Look at the command line arguments and set the *name* variables accordingly.

At least one file name must be present as the first argument: the `mf` file. It may have an extension, or it may omit it to get ´.mf´ added. If there is only one file name, the output file name is formed by replacing the `mf` file name extension by ´.tex´. Thus, the command line `mf foo` implies the use of the METAFONT input file `foo.mf` and the output file `foo.tex`. If this style of command line, with only one argument, is used, the default style file, *plain.mft*, will be used to provide basic formatting.
